Preface

In this thesis I have sought to create a computer model of the NATO standard continuously variable slope delta voice encoding system with sufficient flexibility to permit continued study of the standard's specifications and tolerances. This investigation has started the process of evaluating the proposed NATO standard, however, additional study is necessary to determine the standard's adequacy to assure system interoperability.

I wish to thank my thesis advisor, Capt. Kizer, and the members of the thesis committee, Lt. Col. Carpinella and Capt Seward, for their assistance, guidance, and tolerance during the course of this project.

Jeffrey A. Lersch

Abstract

A computer model of the continuously variable slope delta voice encoding system specified in the draft STANAG on "Analogue/Digital Conversion of Speech Signals for Tactical, Digital, Area Communications Systems", dated June 1978, is developed and implemented in FORTRAN IV. The model's performance is then characterized in terms of idle channel noise, total harmonic distortion, intermodulation distortion, signal-to-noise ratio, and frequency response. For each of these attributes, the system's performance is presented graphically and compared to the criteria established in the draft standard. The model is then exercised by varying the system parameters to the limits imposed by the standard and the resulting performance compared to the previously determined ideal system performance. The results show that the performance characteristics measured are most sensitive to the primary integrator response and output filter response when the system parameters are restricted to the range allowed by the draft NATO standard.

INVESTIGATION OF CONTINUOUSLY VARIABLE SLOPE  
DELTA (CVSD) MODULATOR/DEMODULATOR COMPATABILITY

I. Introduction

A draft NATO standard on the analog to digital conversion of speech signals using continuously variable slope delta (CVSD) modulation is presently being circulated among the military services for comments. The proposed standard, "The Analogue/Digital Conversion of Speech Signals for Tactical, Digital, Area Communications Systems," June 1978, seeks to assure transmission systems interoperability by standardizing the system architecture and setting tolerances on key system parameters. The draft standard (see Appendix A) consists mainly of end-to-end system performance criteria, primarily signal-to-noise ratios and amplitude response characteristics. No standards are specifically established for transmission-end/reception-end mismatch performance.

The Air Force Communications Command, AFCC/OA, has questioned whether the limited number of specifications given are adequate to assure system performance when the CVSD encoding equipment is not perfectly matched to the decoding equipment. Are the tolerances specified sufficiently narrow to assure no serious signal degradation when the modulator and demodulator parameters differ by the maximum amount allowed by the draft standard? This is the question that this investigation seeks to answer.

Problem Statement Determine the adverse effects on the transmitted signal and their severity when the CVSD encoder and decoder parameters differ within the limits allowed by the draft STANAG on "The Analogue/Digital Conversion of Speech Signals for Tactical, Digital, Area Communications Systems," June 1978.

Approach The approach of this investigation is to perform a computer simulation of the CVSD analog to digital conversion system then evaluate the system's performance under varying external and internal conditions. Initially, a basic mathematical analysis of the system components is performed and mathematical models of the CVSD encoder, decoder and the

input and output filters are developed. These models are then translated into computer subroutines and coded in FORTRAN. In the next section, the tests used to characterize the model are described. These tests consist of the standard voice frequency measurements as, idle channel noise, total harmonic distortion, intermodulation distortion, signal-to-noise ratio, and frequency response. The system is first characterized with the encoder and decoder parameters matched. Each test is performed at frequencies and amplitudes across the normal active range of the system. After system performance under ideal conditions is established, the system parameters are allowed to vary across the ranges allowed by the draft standard and the degradation of the transmitted signal by encoder and decoder parameter mismatching evaluated. The results of the testing are then analyzed to determine which parameter mismatches most seriously degrade system performance and to determine if the degradation is serious enough to prevent signal transmission.

## II. Analog/Digital Conversion System Model

The basic analog/digital CVSD system defined in the draft standard is shown in the block diagram in Figure 1. It consists of four major components, the input and output filters, the CVSD encoder, and the CVSD decoder. Each of these components is discussed in the following sections.

CVSD Encoder Operation The CVSD encoder structure is shown in Figure 2. The bandlimited signal from the input low-pass filter is applied to one input of the comparator and sampled at the clock rate, either 16 or 32 kb/s. Each input sample is compared to an estimate of the signal generated by the encoder feedback network from previous input samples. In this model, the comparator output is +1 if the input sample is greater than the signal estimate and -1 if the input sample is less than the estimate. This polar signal is converted to binary (+1 = 1, -1 = 0) and forms the transmitted data signal. To generate the next signal estimate, the polar signal from the comparator is routed to the input of the slope overload detector.

Slope overload, as defined for this system, is the condition when the last three comparator outputs are identical, either all +1's or all -1's. This indicates that the input signal amplitude is rising or falling, respectively, faster than the encoder can track using the present step size. Other systems define slope overload by different length strings of identical comparator outputs. Strings of two or four identical bits are also commonly used to indicate slope overload. The last three comparator outputs are stored in a shift register within the slope overload detector and combinational logic circuits used to determine if a slope overload condition exists. The slope overload detector output controls the position of the switch shown in the block diagram. Under normal conditions, when slope overload does not exist, the switch is in the  $V_{\min}$  position. Upon occurrence of slope overload, the switch position is changed and  $V_{\max}$  is applied to the input of the syllabic filter.

The syllabic filter is generally a simple single pole RC filter

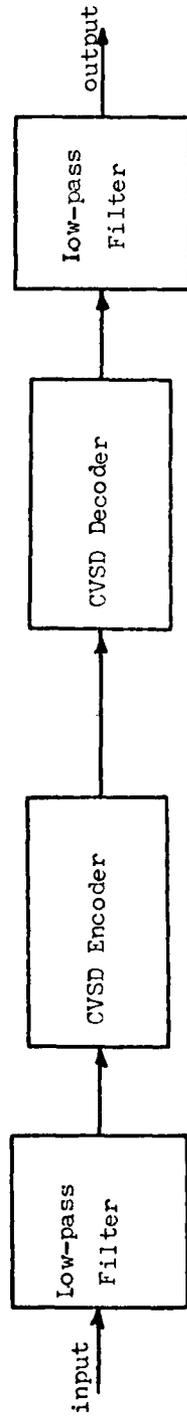

Figure 1. The CVSD Signal Processing System

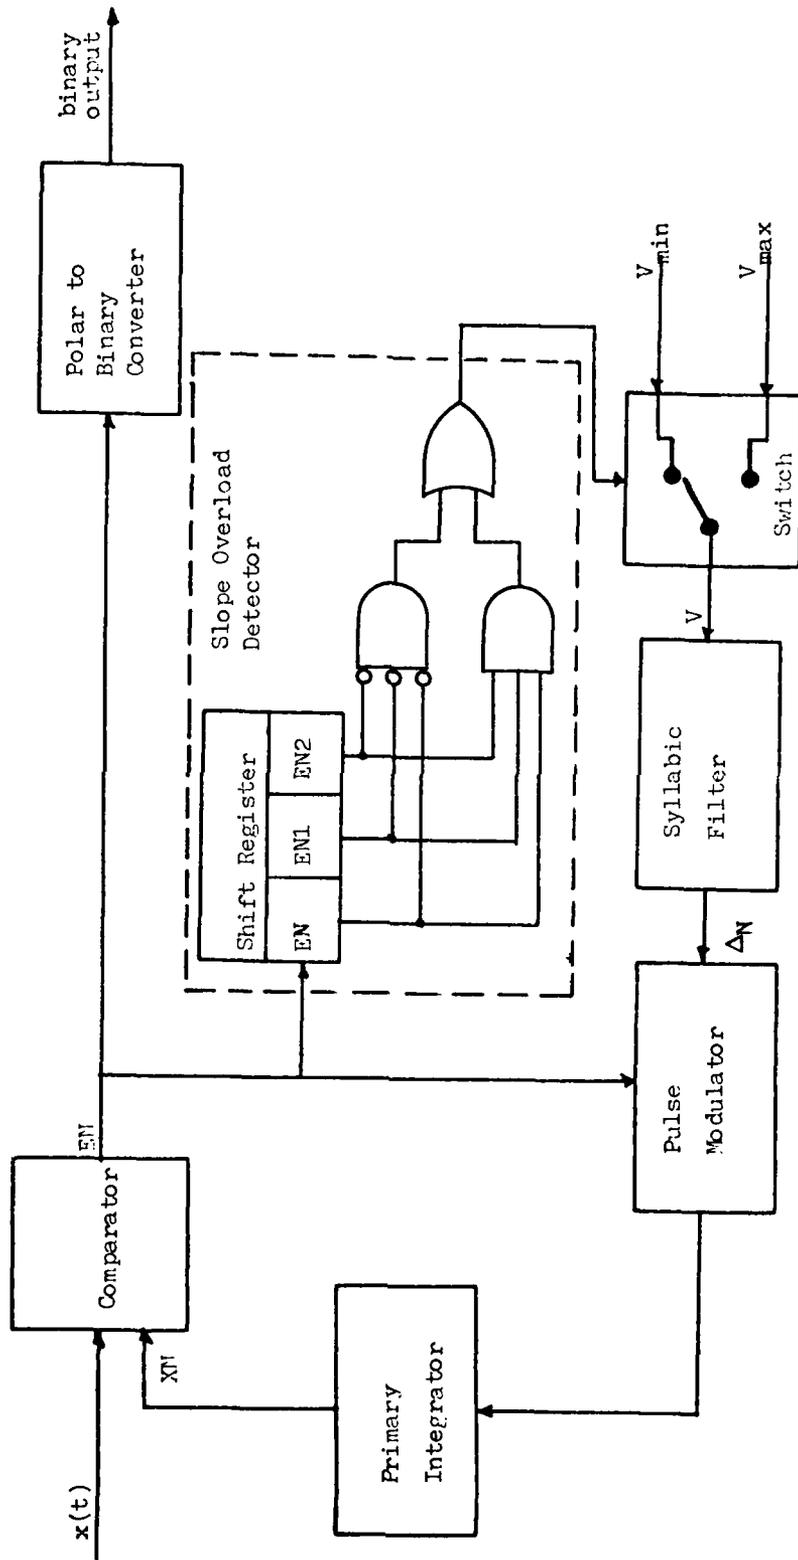

Figure 2. CVSD Encoder Block Diagram

whose output is defined as the step size of the CVSD encoder. The syllabic filter controls the response of the system to the envelope of the speech signal being processed. Prolonged application of  $V_{\min}$  to the input of the syllabic filter causes the output to decrease to a minimum non-zero value that approaches  $V_{\min}$ . Under continuous slope overload conditions,  $V_{\max}$  is continuously applied to the input of the syllabic filter causing the filter output to increase to an average value approaching  $V_{\max}$ . The magnitude of the syllabic filter output is used to control the amplitude of the output pulse of the pulse modulator. Polarity of the pulse is controlled by the last output of the comparator.

The primary integrator responds to the square wave signal from the pulse modulator and its output forms the signal estimate used by the comparator. At the end of each clock period a new estimate is available to be used by the comparator in generating the next binary output and the next signal estimate. The primary integrator's response controls the maximum analog signal frequency that can be processed through the the CVSD analog to digital conversion system. In figure 3, are shown sample waveforms at each stage of the analog to digital conversion process.

Encoder Algorithm The mathematical description of the CVSD encoder operation is largely a description of its component filters, the primary integrator and the syllabic filter. One of the system characteristics specified by the draft standard is the primary integrator response. The impulse response, in its simplest form, is given as,

$$a(t) = e^{-2\pi f_{cl} t} \quad (1)$$

where

$f_{cl}$  = the pole frequency of the filter in hertz

The primary integrator input signal is the square wave output of the pulse modulator, which for a single pulse can be described as,

$$\begin{aligned} a(t) &= 0 && t < 0 \text{ and } t > T \\ &= a && 0 \leq t \leq T \end{aligned}$$

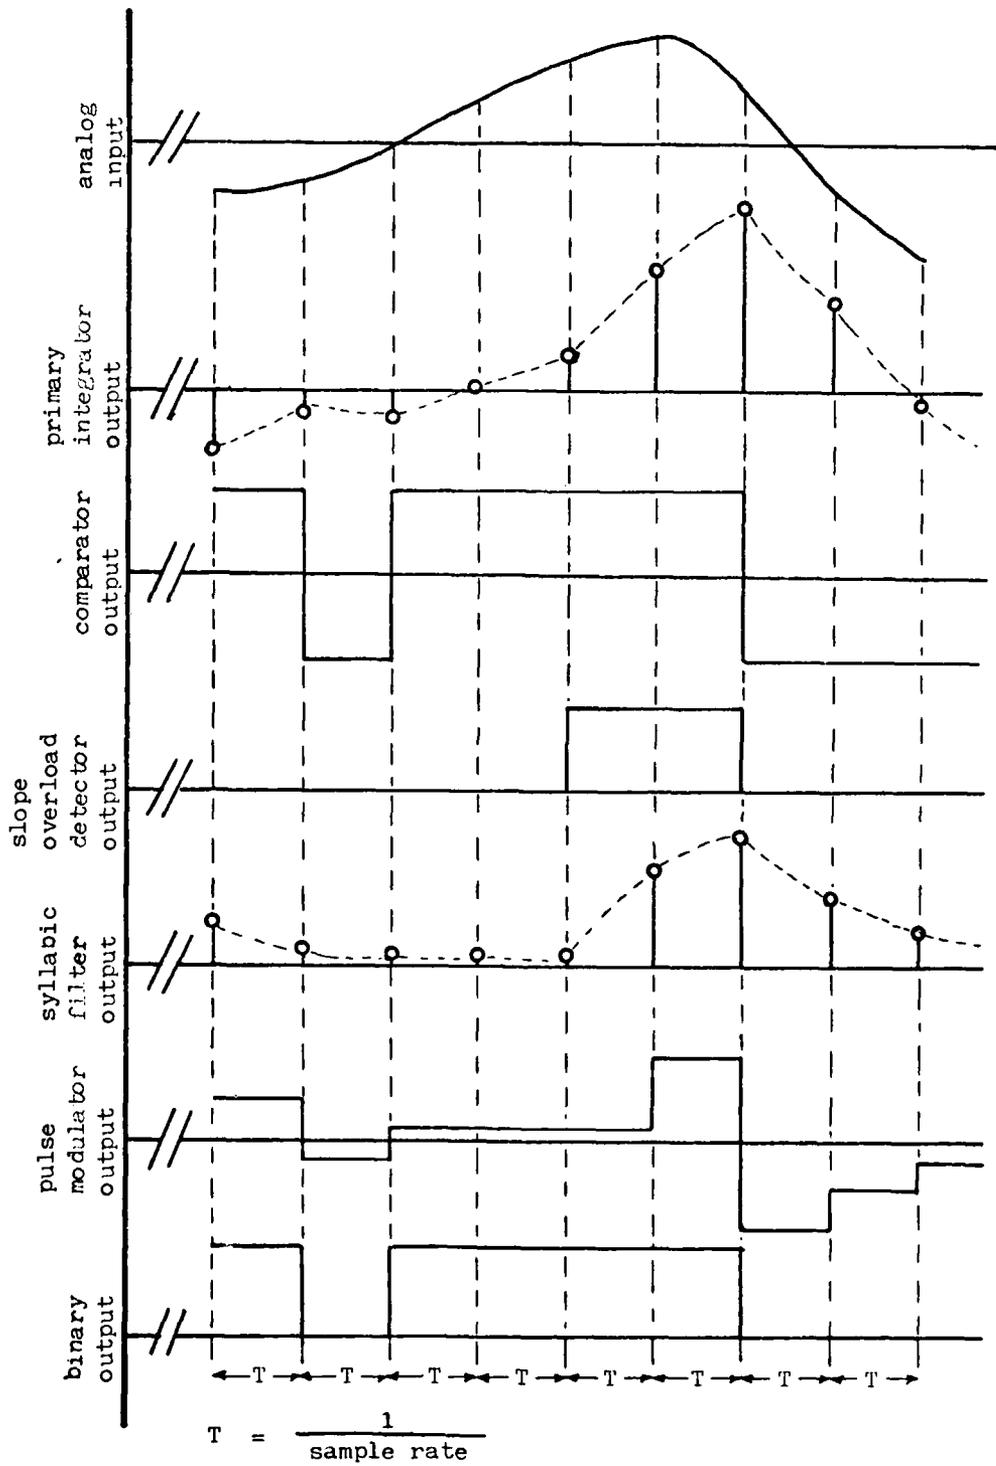

Figure 3. Sample Waveforms at Various Points in the Encoder

where

$$T = \frac{1}{\text{sample rate}}$$

The primary integrator output is determined by convolving the filter impulse response with the input signal.

$$\begin{aligned} x(t) &= a(t) * \alpha(t) = \int_{-\infty}^{\infty} a(\tau) \alpha(t - \tau) d\tau \\ &= 0, \text{ for } t < 0 \\ &= \frac{a}{2\pi f_{c1}} [1 - e^{-2\pi f_{c1} t}] , \text{ for } 0 \leq t \leq T \quad (3) \\ &= \frac{a}{2\pi f_{c1}} [1 - e^{-2\pi f_{c1} T}] e^{-2\pi f_{c1} (t - T)} , \text{ for } t > T \end{aligned}$$

Since the primary integrator output is of interest only at the end of each clock period, when it is used for comparison with the input analog signal, the continuous equations developed above can be simplified as follows. For  $t = nT$ ,

$$x_n = \frac{a}{k_1} (1 - \alpha) \alpha^{n-1}, \quad n = 1, 2, \dots, N \quad (4)$$

where

$$\alpha = e^{-2\pi f_{c1} T}$$

$$k_1 = 2\pi f_{c1}$$

Using superposition, the primary integrator output as the result of a series of  $N$  pulses can be described as,

$$\begin{aligned} x_N &= \frac{1}{k_1} [a_N (1 - \alpha) + a_{N-1} (1 - \alpha)\alpha + \dots + a_1 (1 - \alpha)\alpha^{N-1}] \\ &= \sum_{n=0}^{N-1} \frac{a_{N-n}}{k_1} (1 - \alpha) \alpha^n, \quad \text{for } n = 1, 2, \dots, N \quad (5) \end{aligned}$$

This expression can also be defined recursively, depending only on the present input and the last output. This definition can be used to simulate the CVSD encoder on a computer.

$$x_N = x_{N-1} \alpha + (1 - \alpha) \frac{a_N}{k_1} \quad (6)$$

The analysis of the syllabic filter output follows identically that of the primary integrator. The impulse response of the syllabic filter is,

$$\beta(t) = e^{-\left[\frac{2\pi t}{t_c}\right]} \quad (7)$$

where

$$t_c = \text{the time constant of the syllabic filter}$$

The recursive expression for the syllabic filter output is,

$$\Delta_N = \Delta_{N-1} \beta + (1 - \beta) \frac{V_N}{k_2} \quad (8)$$

where

$$k_2 = \frac{2\pi}{t_c}$$

$$\beta = \exp\left[-\frac{2\pi T}{t_c}\right]$$

$$V_N = \text{either } V_{\max} \text{ or } V_{\min}, \text{ the syllabic filter input}$$

Encoder Computer Subroutine Equations (6) and (8) are implemented in the subroutine used to perform the CVSD encoding for this investigation. Figure 3 is a flowchart of the subroutine used for encoding and Appendix B is the FORTRAN code used. All of the system defining parameters are transmitted to the subroutine through the calling statement. Encoding is performed on an array basis. The analog signal to be analog to digital converted is first sampled at the clock rate and the samples placed in the input array, which is of size  $1 \times N$ , where  $N$  is the number of samples. All of the samples are encoded by the subroutine and the binary data stream placed in the output array before the subroutine returns control

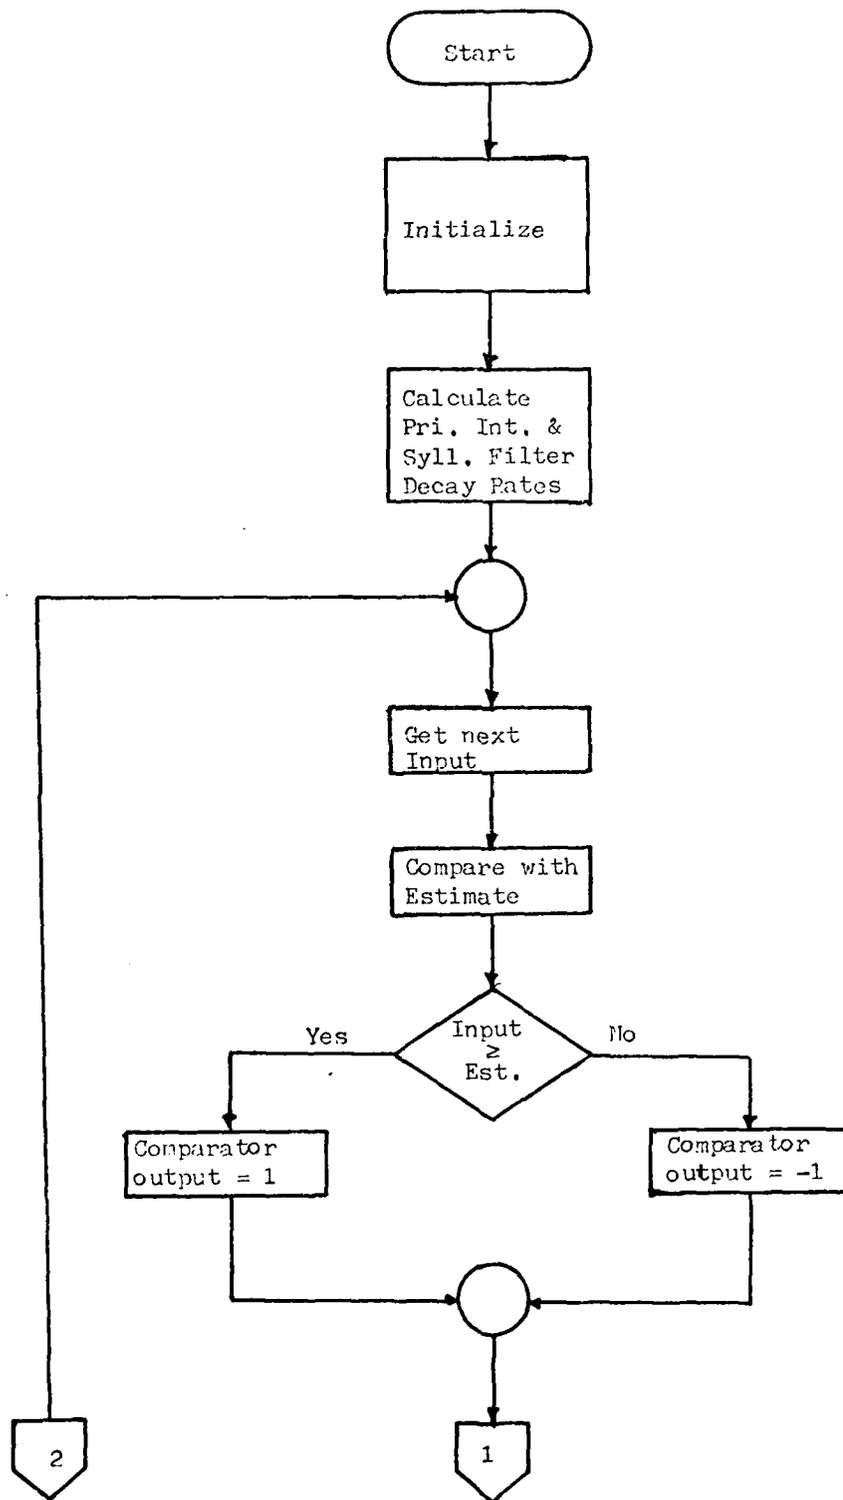

Figure 4. CVSD Encoder Subroutine Flowchart

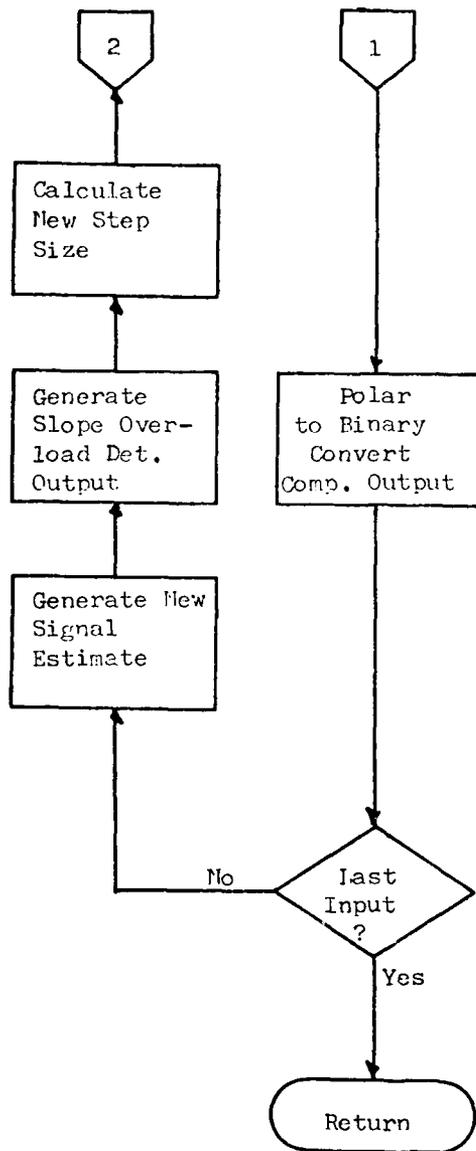

Figure 4 (continued). CVSD Encoder Subroutine Flowchart

to the calling program.

Two of the primary system defining parameters,  $V_{MAX}$  and  $V_{MIN}$  must be generated by subroutine  $V_{MAXOPT}$  (appendix I) before the encoder subroutine is called. It should be noted that the constants  $k_1$  and  $k_2$  derived in equations (5) and (8) are not specifically included in the program statements defining the primary integrator and syllabic filter responses but are expected to be included in the values calculated for  $V_{MAX}$  and  $V_{MIN}$ .

The variable  $DC$  in the subroutine is the duty cycle of the slope overload detector. This variable is not used during the encoding process. Instead, it is used only by  $V_{MAXOPT}$  when the values of  $V_{MAX}$  and  $V_{MIN}$  are being determined.

CVSD Decoder Operation The CVSD decoder circuit is identical to the encoder feedback circuit. A block diagram of the decoder is shown in figure 5. The only difference between the decoder and the encoder is that the decoder has no comparator. The binary signal from the encoder is applied directly to the slope overload detector and the output signal is taken from the primary integrator. The signal estimate generated in the decoder is identical to that generated in the encoder, if the parameters of each unit are identical. However, at the decoder the signal estimate is of interest at all times and not just at the sample periods, as the decoder signal estimate is the approximation of the analog signal transmitted by the CVSD encoder. Figure 6 shows sample waveforms at various points within the decoder. The waveforms are identical to those shown in figure 3, except that the decoder primary integrator output is shown as a continuous signal.

Decoder Algorithm Since the decoder circuit is identical to the encoder circuit without the comparator, the mathematical analysis developed for the encoder is also applicable to the decoder. One exception, however, is that the simplification used to obtain equation (4) is not generally applicable to the decoder since the primary integrator output in the decoder is required to be continuous. The recursive expression for the decoder output is,

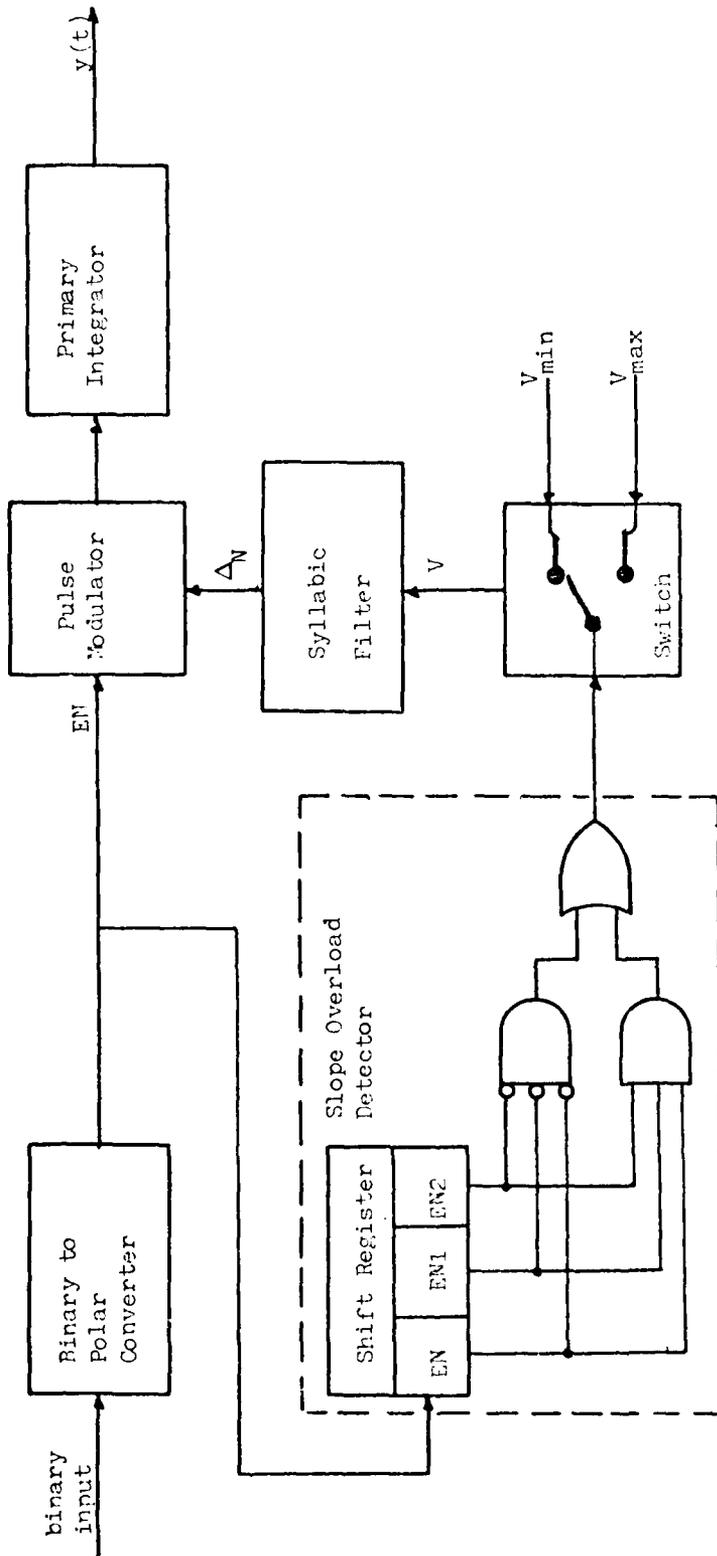

Figure 5. CVSD Decoder Block Diagram

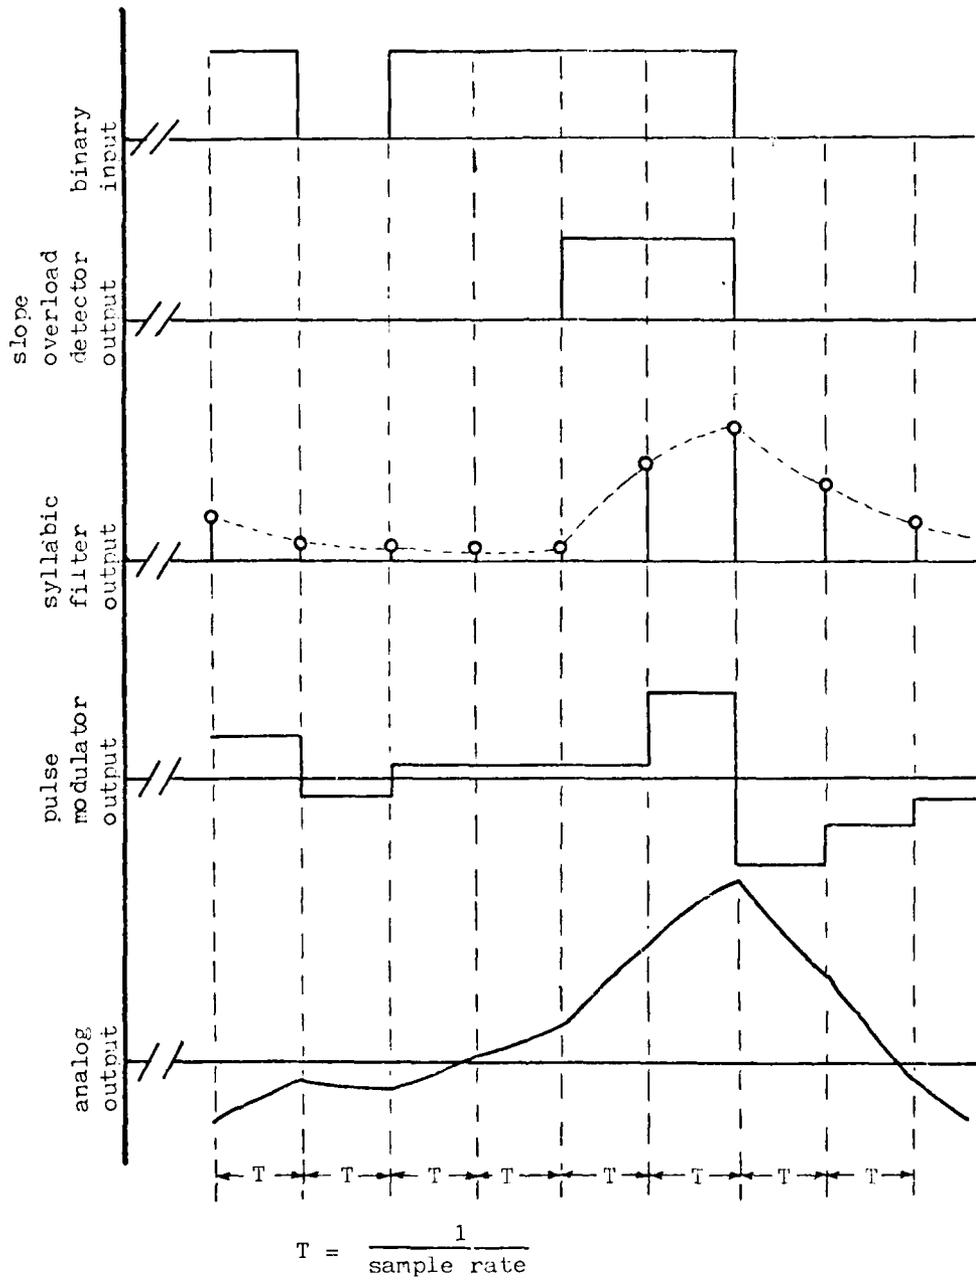

Figure 6. Sample Waveforms at Various Points in the Decoder

$$y(t) = \left[ y(t - [N-1]T) \right] e^{-k_1 t} + (1 - e^{-k_1 t}) \frac{a_N}{k_1} \quad (9)$$

for  $(N-1)T < t < NT$

where

$$T = \frac{1}{\text{sample rate}}$$

$$k_1 = 2\pi f_{c1}$$

$a_N$  = the primary integrator input for  $(N-1)T < t < NT$

$f_{c1}$  = the pole frequency, of the primary integrator in hertz

Analysis of the decoder syllabic filter is identical to that of the encoder syllabic filter and equation (8) also applies to the decoder.

$$\Delta_N = \Delta_{N-1} \beta + (1 - \beta) \frac{V_N}{k_2} \quad (8)$$

where

$$k_2 = \frac{2\pi}{t_c}, \quad \Delta_N = \text{the syllabic filter output}$$

$$\beta = \exp\left[-\frac{2\pi t_c}{t_c}\right]$$

$V_N$  = either  $V_{max}$  or  $V_{min}$ , the syllabic filter input

Decoder Computer Subroutine Using equations (6) and (8), the decoding subroutine is implemented as shown in the flowchart in figure 7. Equation (9) is not used since the straight line approximation provided by the Calcomp plotter provides a sufficiently accurate representation of the decoder output for this investigation. Except for the elimination of the comparison step used in the encoder subroutine, the decoder subroutine is nearly identical to that of the encoder. All comments applicable to the encoder subroutine are also applicable to the decoder subroutine. The FORTRAN code for the decoder subroutine is attached in Appendix C.

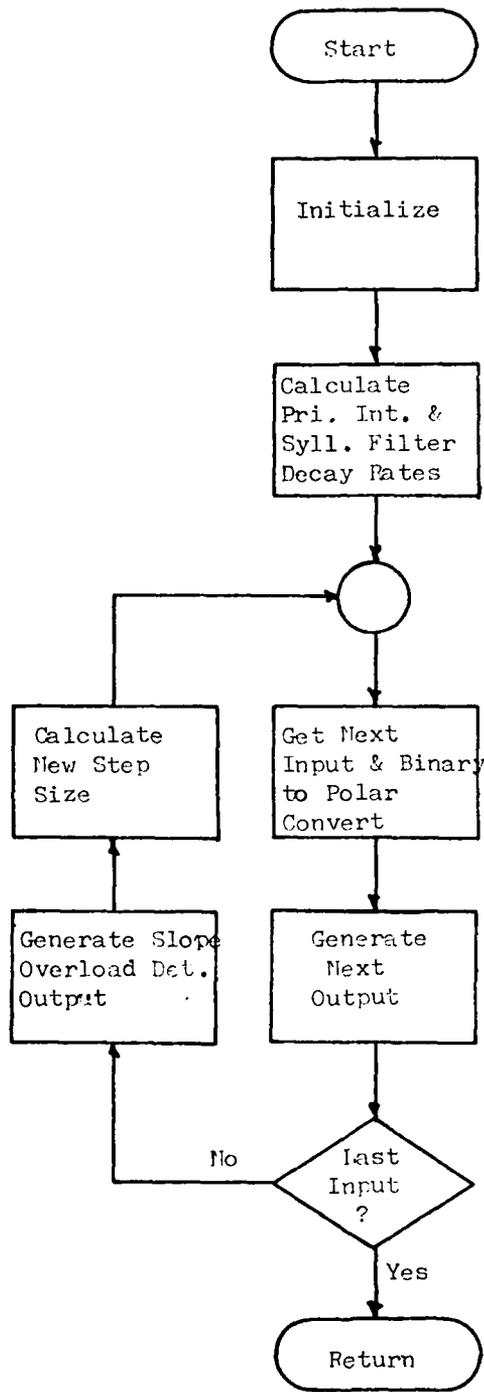

Figure 7. CVSD Decoder Subroutine Flowchart

Encoder and Decoder Parameters From the expressions developed in the preceding sections describing the CVSD encoder and decoder, it can be seen that there are four parameters that determine the characteristics of the encoder and decoder. They are,  $f_{c1}$  for the primary integrator,  $t_c$  for the syllabic filter, and  $V_{max}$  and  $V_{min}$  whose value determines the magnitude of the step sizes.

The draft standard specifies the value of  $f_{c1}$  explicitly in paragraph 3.2. When the primary integrator consists of a single pole filter, the value of  $f_{c1}$  is required to be between 100 and 300 Hz. Other poles and zeros can be added to the primary integrator, in accordance with the draft standard, however, only  $f_{c1}$  is required. In this investigation, the single pole version of the primary integrator is used in the CVSD encoder and decoder models.

For the syllabic filter, the draft standard does not specify the value of  $t_c$  directly. Instead,  $t_c$  is specified in terms of the decoder output signal when a given input is applied to the encoder. When the analog input signal at 300 Hz is stepped from -42 dBm0 to 0 dBm0, the decoder output signal is required to achieve 90% of its final value within 2 to 4 milliseconds after the output signal starts to rise. (NOTE: For this system, the standard specifies the reference test level point to be -4 dBm. So, a -42 dBm0 is actually -46 dBm. All measurements taken in this investigation are stated in dBm0, unless explicitly stated otherwise.)

The values of  $V_{max}$  and  $V_{min}$  are also not specified directly by the draft standard, but are specified in terms of the syllabic filter output. The syllabic filter output, which has previously been defined as the step size of the encoder and decoder, is required to be linear as a function of the slope overload detector duty cycle. The slope overload detector duty cycle is defined as the ratio of the number of times slope overload is detected to the number of samples in the same period. In paragraph 3.4 of the draft standard, the step size is shown as varying linearly as the duty cycle ranges from 0 to .5. The step size ratio, the ratio of the syllabic filter output when an 800 Hz, 0 dBm0 signal is applied to the encoder input, to the syllabic filter output when the encoder input is grounded is required to be  $34 \text{ dB} \pm 2 \text{ dB}$ . This specification

in combination with the specifications for  $f_{c1}$  and  $t_c$  determine the values of  $V_{max}$  and  $V_{min}$ .

Due to the fact that the parameters interact with each other, the values of  $t_c$ ,  $V_{max}$ , and  $V_{min}$  need to be determined recursively. A value of  $f_{c1}$  is chosen within the range given by the standard and an estimate of  $t_c$  chosen near its expected value. The syllabic filter determines the system response to the amplitude modulation of a voice signal. As the highest frequency in the envelope of the voice signal is generally about 100 Hz,  $t_c$  is estimated to be the reciprocal of this frequency or .01. A nominal step size ratio is given by the draft standard to be 34 dB. These three parameters are used to calculate the values of  $V_{max}$  and  $V_{min}$ . Figure 8 is the flowchart of the program that calculates these values using the subroutines shown in figures 9 and 10, then plots the resulting syllabic filter output as a function of slope overload detector duty cycle.

Initially, estimated values of  $V_{max}$  and  $V_{min}$  are used and the slope overload detector duty cycle and system step size ratio calculated when an 800 Hz, 0 dBm0 test signal is input to the CVSD encoder. If the calculated values are not within the tolerances specified,  $V_{max}$  and  $V_{min}$  are adjusted and the calculations repeated. This process is continued until values of  $V_{max}$  and  $V_{min}$  are determined that produce a slope overload detector duty cycle of  $.5 \pm 1\%$ , and a step size ratio within .01% of the input value.

After determining the values of  $V_{max}$  and  $V_{min}$ , the entire CVSD system is tested to determine if the rise time requirement is met using the parameters that have been calculated. The flowchart of the test program is shown in figure 11. To determine the system rise time, a test signal consisting of alternate series of 500 samples of an 800 Hz, -42 dBm0 sine wave and 500 samples of the 800 Hz sine wave at 0 dBm0. The initial series at -42 dBm0 initialize the storage elements of the slope overload detectors in both the encoder and decoder and get the system into an initial steady-state condition. After processing the test signal through the system, the output signal is plotted in the vicinity around one of the steps in input signal power. The system rise time is then determined graphically. Figure 12 shows a sample output from this program for both the 16 and 32 kb/s sample rates. This test was performed with  $f_{c1} = 100$  Hz, step size ratio = 34 dB,  $t_c = .01$  for the 16 kb/s sample rate, and

$t_c = .02$  for the 32 kb/s test. Table I summarizes the parameters and the range of each that will still result in a system that complies with the performance criteria set by the draft standard.

TABLE I  
PARAMETER SUMMARY

Parameter	Sample Rate	
	16 kb/s	32 kb/s
Primary Interpolator - $f_{d1}$	100 - 300 Hz	
Syllabic Filter - $t_c$	.01 - .015	.02 - .025
Step Size Ratio	34 dB $\pm$ 2 dB	

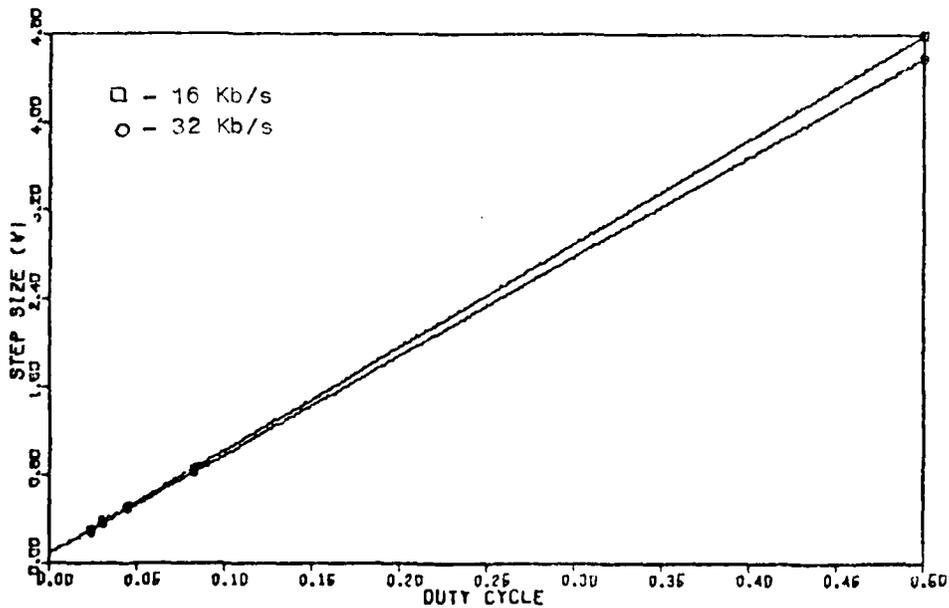

Figure 13. Syllabic Filter Output (step size) as a Function of Slope Overload Detector Duty Cycle for both 16 and 32 kb/s Sample Rates

Input and Output Low-Pass Filters The last of the major components making up the CVSD analog/digital conversion system are the input and output filters. These filters are used to limit both the input and output signal spectrum to the voice band frequencies only. For telephonic communications, the voice band is generally considered to be those frequencies less than 3600 Hz. For optimal system performance, these filters should have a very sharp cut-off and high loss characteristics in the stop band.

The purpose of the input filter is to limit the input signal spectrum to prevent aliasing due to the sampling process. When the input signal is sampled, in addition to the input spectrum, the output spectrum also contains sum and difference frequency components centered around the sample frequency. If the input spectrum were to contain frequencies very much larger than the desired spectrum, aliasing or interference would occur when the difference frequencies fell into the baseband spectrum. For this model, the input filter is considered to be an ideal low-pass filter. The test signal generator output spectrum is limited to the voice band frequencies only, with no components falling outside that range. This simulates a low-pass filter with zero insertion loss in the pass band and infinite loss in the stop band.

The function of the output filter is also to limit the signal to the voice band, however, in this case, the components outside the original input spectrum are produced by the non-linearities of the processing system. The output filter smooths the signals and eliminates the harmonic components above the voice band. This filter may have the same characteristics as the input filter or may have a narrower pass band to improve performance. The filter chosen for this model is a maximally flat, linear phase symmetrical finite impulse response (FIR) filter. The model of this filter was developed by J.F. Kaiser of the Digital System Research Department of the Bell Laboratories. Reference 1 provides more complete documentation of the filter model. There are two parameters that define the response of the filter, beta and gamma. Figure 14 shows the response of the filter generated by this program and where beta and gamma are defined. Beta is the normalized center frequency of the transition region and gamma is the normalized width of the region. Normalization is with respect to the sample rate. This filter was chosen for its flat

response in the pass band in order to minimize disturbance of the CVSD encoder/decoder response, since those are the primary system components under investigation. The parameters chosen for the filter are  $\beta = .1875$  and  $\gamma = .1$  for the 16 kb/s sample rate and  $\beta = .1$  and  $\gamma = .1$  for the 32 kb/s sample rate. Table II lists the filter coefficients generated by the program and figure 15 shows the frequency response for both filters.

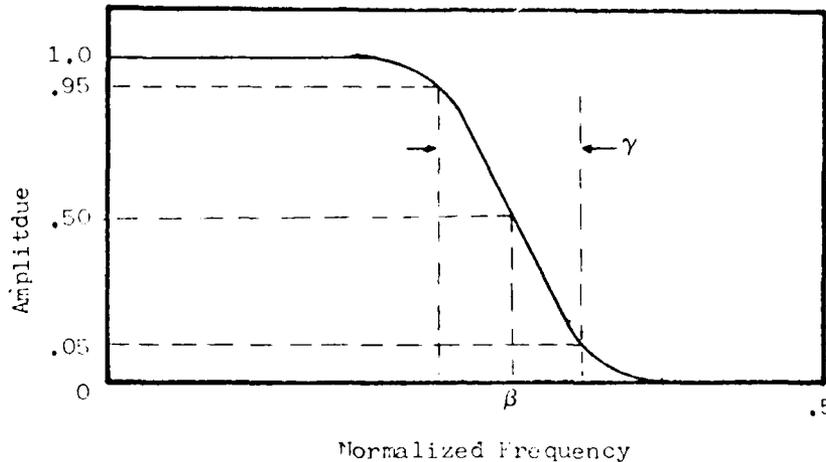

Figure 14. Maximally Flat FIR Filter Response Characteristic and Parameter Definition

The center of the transition region for the 16 kb/s filter is 3 kHz and 3.2 kHz for the 32 kb/s filter. As can be seen, the maximally flat characteristic is achieved at the expense of stop band loss. However, it will be shown in the performance results that the system performance meets most of the criteria specified by the draft standard in spite of the poor filter performance.

Filter Subroutines The filter program developed by J.W. Kaiser is used to generate the FIR filter coefficients, however, it has been modified to be a subroutine that returns the coefficient values to the calling program instead of printing them out. These coefficients are produced by FITRGEN then used by subroutine FILTER to actually filter the signal input to the filter. The maximum number of coefficients that can be produced by FITRGEN without program modification is 200. Subroutine FILTER delays the output signal by 200 sample periods so that it has at least

### III. Performance Tests

A model of the continuously variable slope delta analog to digital conversion system is constructed from the component models described in the previous sections. Figure 17 shows the test configuration simulated by the computer model used in this investigation. The system under test is shown in figure 1. In this simulation, the test signal generator is a subroutine that generates samples of a sinusoidal signal that can be composed of up to two frequency components at individually specified amplitudes. The standard test signal used in the performance tests is an 800 Hz sine wave at -20 dBm, unless otherwise stated. As previously indicated, the reference signal level is -4 dBm. All power measurements are made relative to this level. The test signal is generated as an array of 5000 samples for most of the tests performed. This array is then processed through the system, the output array of each system component becoming the input array of the next. The final system output signal is then processed to determine the various signal characteristics. System performance is measured in terms of the commonly used voice frequency tests as, idle channel noise, total harmonic distortion, intermodulation distortion, signal-to-noise ratio, and frequency response. These tests are first performed with the CVSD encoder and decoder parameters matched, then performed again with various combinations of encoder and decoder parameters to show how system performance degrades under mismatched conditions.

Idle Channel Noise Test Idle channel noise is measure of the basic amount of noise that the processing system adds to the output signal. The output signal power is measured while the system input is grounded. Any non-zero power measured is the idle channel noise. Before measuring the idle channel noise, however, the system insertion loss is first set so that the standard test signal experiences no change in power after being processed through the system. Idle channel noise is then measured as,

$$ICN = \frac{1}{N} \sum_{n=1}^N y_n^2 \quad (11)$$

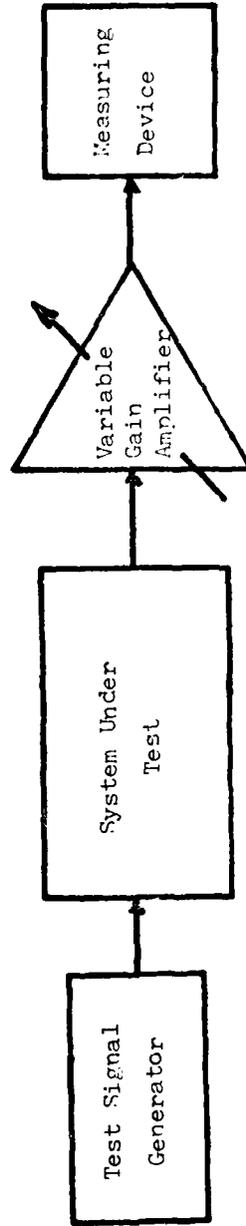

Figure 17. Simulated System Test Configuration

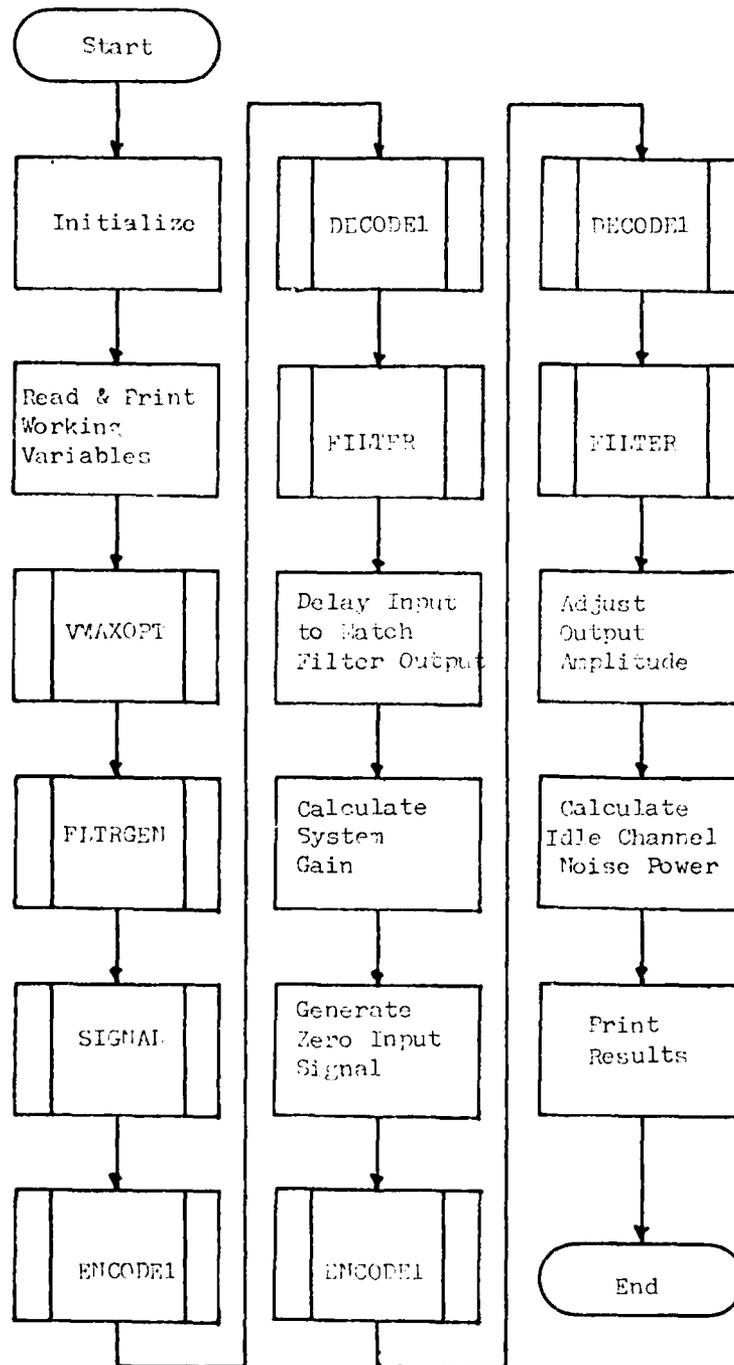

Figure 18. Idle Channel Noise Program Flowchart

where

- $y_n$  = the output signal amplitude
- $N$  = the number of samples

Figure 18 is the flowchart of the idle channel noise test used to measure the CVSD system performance.

Total Harmonic Distortion Test Total harmonic distortion is one of the measures of system non-linearity. The CCITT procedure for measuring total harmonic distortion is to input a single frequency test signal near the center of the system's pass band and measure the magnitude of the harmonic components in the output spectrum. Total harmonic distortion is then calculated by,

$$\text{THD} = \frac{\sqrt{E_2^2 + E_3^2 + \dots + E_N^2}}{E_1} \times 100\% \quad (12)$$

where

- $E_2, E_3, \dots, E_N$  = the RMS voltages of the harmonic signal components in the output spectrum
- $E_1$  = the RMS voltage of the primary signal component in the output spectrum
- $N$  = the largest harmonic within the system pass band

Figure 19 is the flowchart of the computer program used to calculate total harmonic distortion. After processing the single frequency sine wave test signal through the CVSD system, the output signal spectrum is calculated using a fast fourier transform (FFT). Due to the limitations of the FFT, the standard test signal is not used, instead, a 1000 Hz signal at -20 dBm0 is used. The FFT procedure can only measure signal components at multiples of the minimum frequency resolution which is determined by the number of samples in the FFT window. In this case, the window length was specified to be 256 samples, which allowed a frequency resolution of 62.5 Hz at the 16 kb/s sample rate and 125 Hz at the 32 kb/s sample rate. A 1000 Hz test signal was chosen as being both compatible with the FFT and a commonly used test signal in voice frequency measurements.

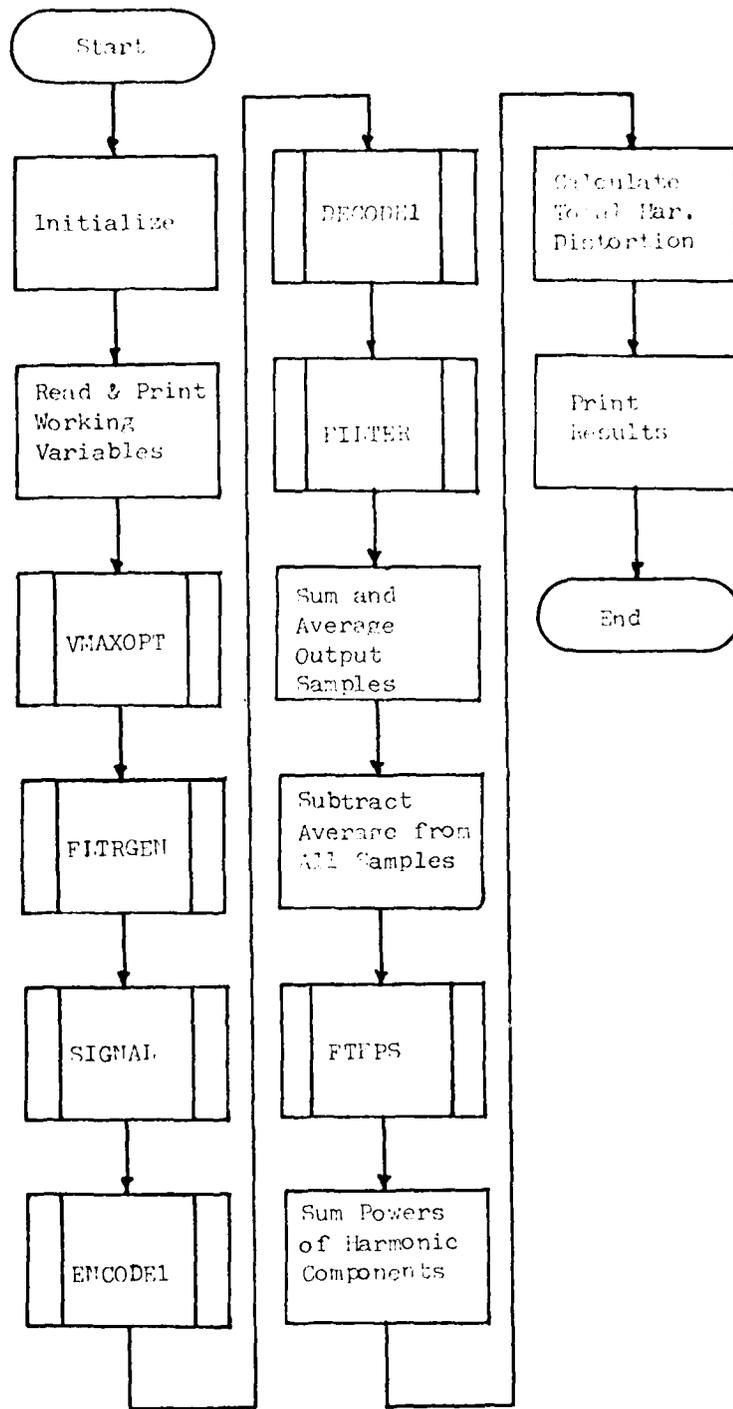

Figure 19. Total Harmonic Distortion Test Program Flowchart (THD)

Intermodulation Distortion The total harmonic distortion test often does not give a complete idea of the system response non-linearities. Intermodulation distortion is another measure of non-linearity used in voice frequency system. The CCITT procedure of measuring intermodulation distortion is to input a composite test signal made of two sinusoidal signals of equal amplitude. The frequencies of the two signals are separated by an amount that the difference frequency is within the pass band of the system. Intermodulation distortion is then calculated by,

$$\text{INTERMOD} = \frac{E_{\text{dif}}}{\sqrt{E_1^2 + E_2^2}} \times 100 \quad (13)$$

where

- $E_{\text{dif}}$  = the RMS voltage of the difference frequency component in the output spectrum
- $E_1$  = the RMS voltage of the first frequency component in the output spectrum
- $E_2$  = the RMS voltage of the second frequency component in the output spectrum

Figure 20 shows the flowchart of the program used to calculate intermodulation distortion for the CVSE system. The procedure is very similar to the total harmonic distortion program except that the spectral components used from the FFT output are the two test frequencies and the difference frequency. The test signal used in the program consists of 750 Hz and 1000 Hz components at -20 dBm.

Signal-to-Noise Ratio Measurement The signal-to-noise ratio is a measure of how accurately the system being characterized reproduces the input signal. A test signal is processed through the system and the resulting output signal compared to the input signal after compensation for the system insertion loss and signal delay. SNR is then calculated by,

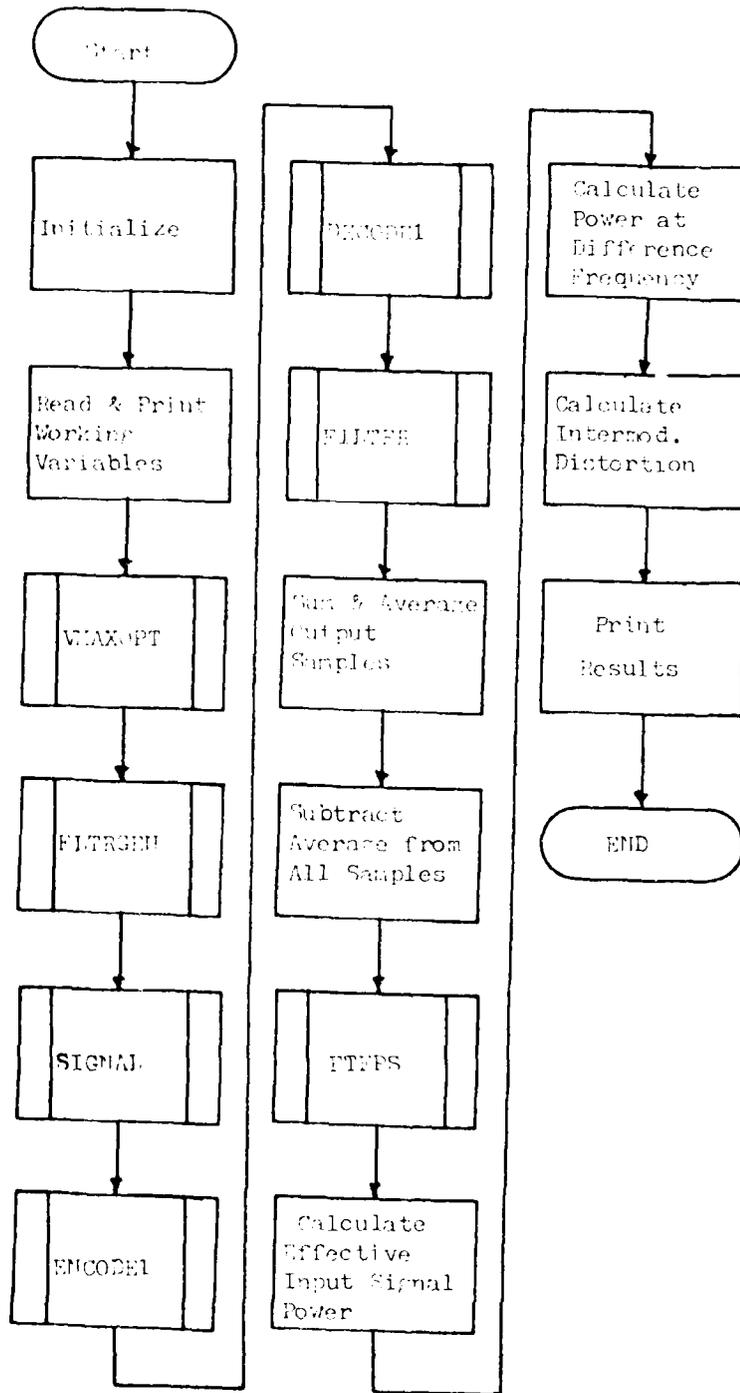

Figure 20. Intermodulation Distortion Test Program Flowchart (INTERED)

$$SNR = \frac{\sum_{n=1}^N (y_n - x_n)^2}{\sum_{n=1}^N x_n^2} \quad (14)$$

where

- $x_n$  = the nth input signal sample
- $y_n$  = the nth output signal sample
- $N$  = the total number of samples

Figure 21 shows the flowchart for the signal-to-noise program used to characterize the CVSD system performance. The standard 800 Hz test signal is used to perform the initial system characterization.

Frequency Response Measurement Two methods of performing frequency response measurement are used in this investigation. The first is flat weighted measurement which is used to determine the frequency response of the entire CVSD system since this is the method for which the draft standard specifies performance criteria. A second method is the frequency selective measurement of the response characteristics. This method is used to investigate the frequency response of the CVSD encoder and decoder only.

Flat weighted frequency response measurement is performed by inputting a single frequency sine wave test signal at a constant amplitude, then measuring the system output signal power. The output signal includes components at frequencies other than the test signal frequency, however, the power of the entire composite signal is measured without filtering. The measured gain variations are then plotted and scaled such that the 800 Hz measurement is 0 dB. The flowchart of the program using this procedure is shown in figure 22.

Frequency selective measurement of frequency response uses the same test procedure except only the magnitude of the output signal component at the test frequency is measured. The other components of the composite output signal are not included in this measurement. The measurements are then scaled and plotted such that the 1000 Hz measurement is 0 dB. Figure 23 is the flowchart of the program to perform the frequency selective measurements. The 1000 Hz measurement is used as the

reference value since the fast fourier transform used to calculate the  
output signal spectrum cannot measure the component at 800 hz.

#### IV. Test Results

The results of the tests described in the previous section are presented here. Each test was first performed with the standard 800 Hz test signal, while the CVSD encoder and decoder parameters were matched. This test characterized the ideal system performance with the system parameters at their nominal values. Next, the tests were performed allowing the system parameters to vary across the ranges shown in Table I and using test signals that varied in frequency and power across their normal dynamic ranges, while still maintaining encoder/decoder match. Finally, the test were repeated again with the encoder parameters held constant at one extreme of the permissible values and the decoder parameters allowed to range to the opposite extreme. Each test was performed changing one variable at a time while the other were held at their nominal values.

Idle Channel Noise The results of the idle channel noise tests are shown in figure 24. For each sample rate, the idle channel noise performance improves as the step size ratio increases. This results from the decrease in minimum step size as the step size ratio increases. The output signal depends entirely on the minimum step size when the system input is zero or grounded. Since the minimum step size is defined to be non-zero, the output signal will alternate positive and negative around zero attempting to approximate the zero input signal. The smaller the deviation from zero, the less the power in the output signal and the better the idle channel noise performance. System performance exceeds the criteria specified in the draft standard. Idle channel noise is -88 dBm0 vs. the specified -50 dBm0 at 16 kb/s sample speed and -97 dBm0 vs. -60 dBm0 at 32 kb/s.

Encoder/decoder parameter mismatch has no effect on idle channel noise. This is a result of the fact that no matter what the encoder's parameters, the output will always be alternating ones and zeros when the encoder input is grounded. Therefore, the input signal at the decoder will always be the same and the output signal will only be affected by the decoder parameters. The idle channel noise performance under mismatched conditions will be the same as shown in figure 24 where the

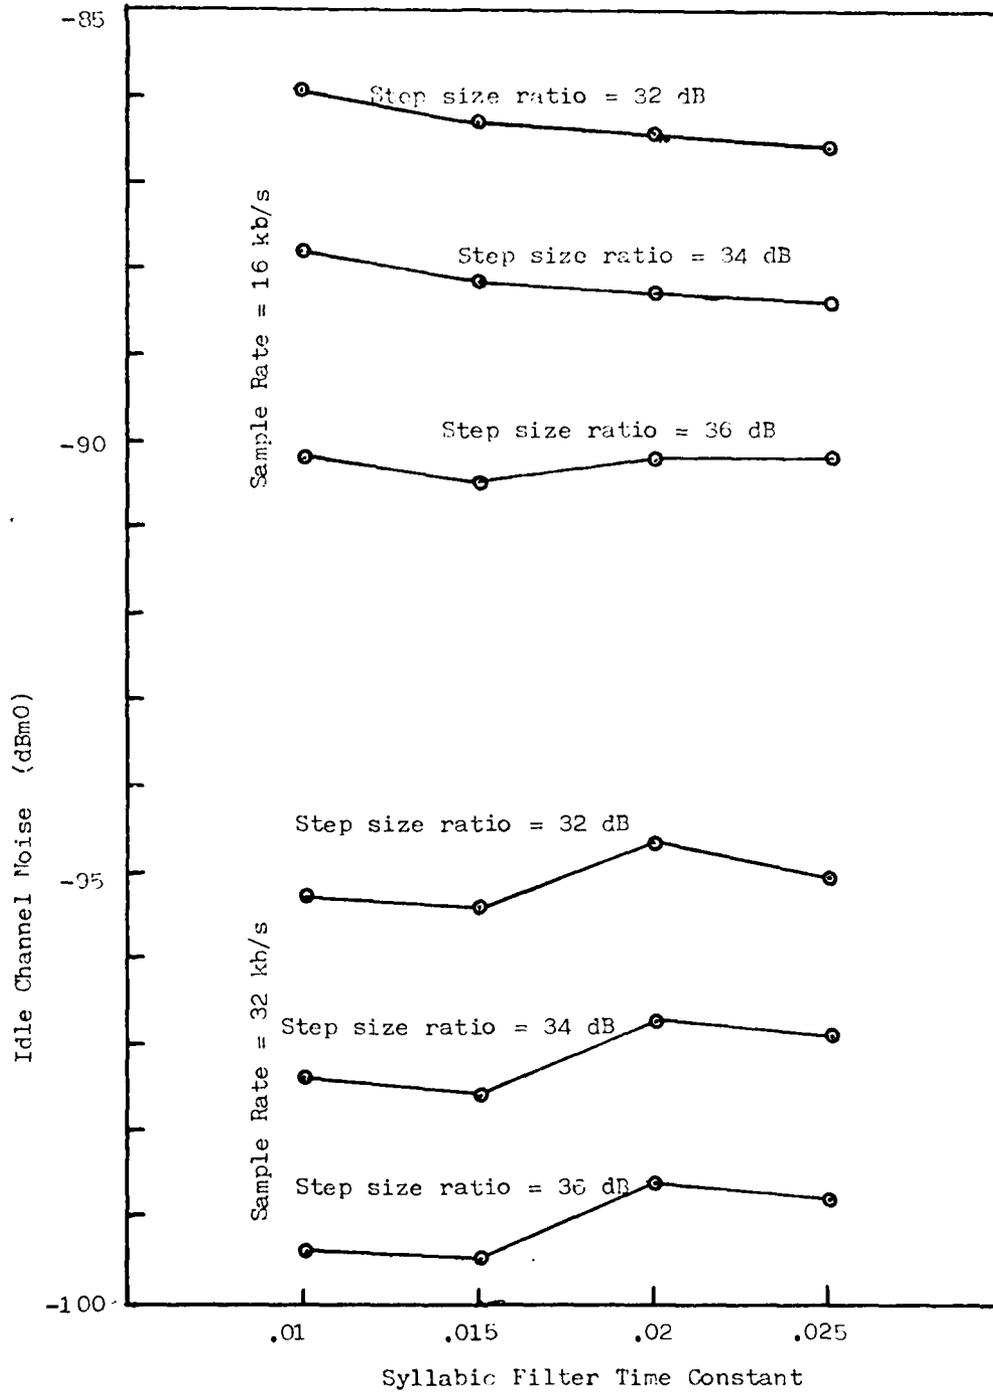

Figure 24. CVSD Signal Processing System Idle Channel Noise Performance

parameters are those of the decoder.

Total Harmonic Distortion The draft standard specifies no maximum total harmonic distortion for the CVSD system, however, it is generally accepted that distortion levels of less than 20% will not usually be objectionable to the system users. As can be seen from the test results shown in figure 25, system performance at the 16 kb/s sample rate exceeds this limit by 4-8%. System performance when the sample rate is increased to 32 kb/s improves substantially. The total harmonic distortion level drops to approximately 6%. Figure 26 shows that the distortion level at both sample rates is relatively constant for all input power levels within the normal operating range except at the very low power levels. When the encoder and decoder parameters are mismatched, the total harmonic distortion performance shows some degradation as figures 27, 28, and 29 indicate. The largest amount of deviation from the matched system performance occurs at the very low power levels where the impact will have the least effect. As figure 29 shows, total harmonic distortion is most sensitive to mismatches of the encoder and decoder primary integrator pole frequencies. Syllabic filter time constants and step size ratios have minimal impact on the system performance when mismatched, however, all have the most impact at the very low input power levels.

Intermodulation Distortion Intermodulation distortion performance for the system model with nominal parameter values is shown in figure 30. As is the case with the total harmonic distortion test, the draft standard provides no performance criteria. In general, intermodulation levels of more than 4-5% will be objectionable to a system user. At the 16 kb/s sample rate, the intermodulation distortion measured ranges from 1 to 5% depending on the syllabic filter time constant used. The distortion falls to approximately 1% when the sample rate is increased to 32 kb/s. Figure 31 shows the system intermodulation response as the input signal power is varied. System non-linearities cause the distortion levels to rise at the very low signal levels and at the high input power levels. Across the normal operating levels between -10 dBm0 and -30 dBm0, the distortion is generally less than 5%. When the encoder and

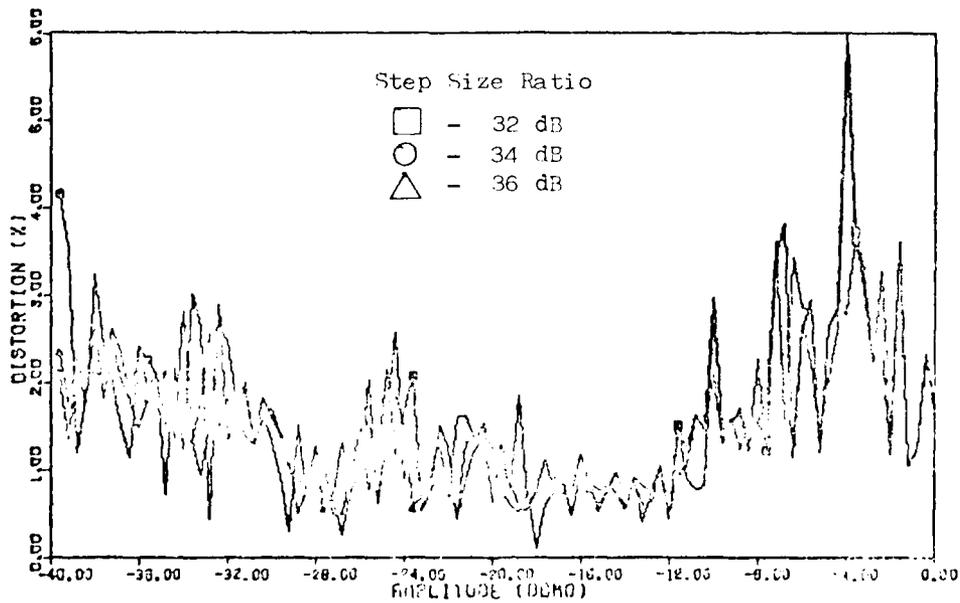

Figure 31b. CVSD System Intermodulation Distortion Performance vs. Input Signal Power with Encoder and Decoder Parameters Matched at 32 kb/s Sample Rate (750 and 1000 Hz Test Signal)

and decoder are mismatched, the intermodulation distortion performance shows the same characteristics as the total harmonic distortion. The step size ratio and syllabic filter time constant have a minimal impact on system performance as shown by the results in figures 32 and 33. When the primary integrators have differing pole frequencies, the intermodulation distortion measurements show more deviation from the matched system performance as shown in figure 34.

Signal-to-Noise Ratio Figures 35 to 43 show how the system ideal signal-to-noise performance changes with variations in system parameters and input test signals. The SNR performance under matched conditions with the standard test signal shows very little variation with differing values of step size ratio, syllabic filter time constant, and primary integrator pole frequency. Signal-to-noise ratio vs. input frequency performance meets the criteria set by the draft standard across most of the voice band. Encoder/decoder mismatches of step size ratio and syllabic filter time constant have very little impact on system performance. A mismatch of the primary integrator pole frequencies, however, have a much larger effect on system performance. The SNR is degraded below the criteria set by the draft standard, with the largest deviation from the ideal performance occurring at the lower frequencies. At the 16 kb/s sample rate the SNR is lowered by about 5 dB and at the 32 kb/s speed, about 4 dB.

Signal-to-noise ratio performance vs. input signal power fails to meet the criteria established in the draft standard. At input levels below approximately -10 dBm0 the model's performance falls below the desired level. Trends in system performance as the result of variations in the system parameters can be observed in spite of this poor performance, as shown in figures 40 to 43. Matched system performance minimal change as the system parameters are varied across the ranges specified in Table I. When the encoder and decoder are not matched, SNR, like total harmonic distortion and intermodulation distortion, shows little deviation from the matched system performance except at the very low signal levels. SNR shows the most change from ideal system performance when the primary integrator pole frequencies are mismatched.

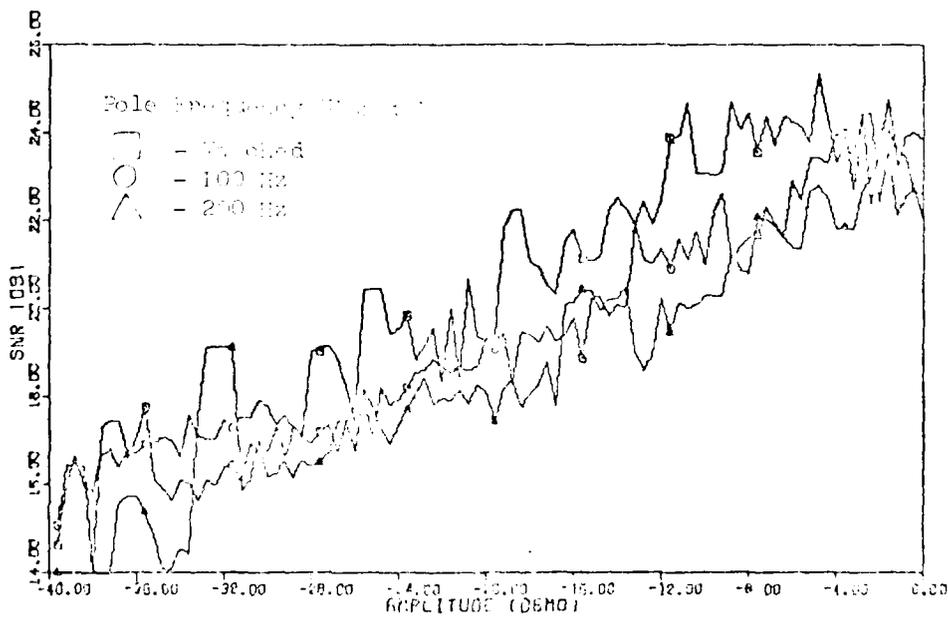

Figure 4b. CVSD System Signal-to-Noise Performance vs. Input Signal Power with Encoder and Decoder. Primary Integrator Pole Frequencies Matched at 32 kb/s Sample Rate. (100 Hz Test Signal).

Frequency response The system frequency response characteristics are specified in the draft standard when measured by the flat weighted method. The results of the tests performed using this technique are shown in figures 44 to 47. The computer model's performance complies with the specified criteria except at the top end of the voice band. The model's response rolls off sharply at approximately 3 kHz. While the draft standard allows some roll-off, the response is not allowed to break sharply until 6 kHz. Variations in the system parameters have very little effect on the response characteristics when the encoder and decoder are matched. Under mismatched conditions, frequency response performance follows the same pattern as that established in the previously described tests. The step size ratio and syllabic filter time constant have minimal impact, while the primary integrator pole frequency causes increased deviation from the matched system performance.

Using the frequency selective measurement technique, the response characteristics of the CVSD encoder and decoder connected back-to-back without the input or output filters were measured. The results are shown in figures 48 to 51. These tests show that the response rolls off at  $\frac{1}{2}$  the sample frequency at both the 16 and 32 kb/s sample rates. At 4 kHz for the 16 kb/s sample rate and 8 kHz for the 32 kb/s sample rate the frequency response curves break sharply. Encoder and decoder mismatch has practically no effect on the frequency response of these system components. The primary integrator pole frequency shows slightly more effect on the response than the other parameters. Its effect is mainly at the very low frequencies in the voice band.

## V. Conclusions and Recommendations

The test results show that the computer model meets most of the performance criteria set by the draft standard when the system parameters are matched and at their nominal values. The output filter does not have the stop band loss characteristics specified in the standard and as a result, the system performance is marginal. Signal-to-noise ratios fall below the established criteria when the input power is less than -10 dBm0. In spite of this, the general effects of variations in the system parameter values and encoder/decoder mismatches can be observed in the test results.

1. When the encoder and decoder are matched, changes in the step size ratio, syllabic filter time constant, and the primary integrator pole frequency values within the tolerances allowed by the draft standard have a negligible effect on the transmitted signal.

2. If the step size ratio or the syllabic filter time constant are not the same in both the encoder and the decoder, the effect of the mismatch on the transmitted signal is negligible except at input power levels less than -32 dBm0. At these levels, the effects would not be noticeable to the system users.

3. System performance is most sensitive to encoder and decoder primary integrator pole frequency mismatches. All the performance tests show a larger deviation from the matched system performance when the primary integrators are mismatched. This type of parameter mismatch dominates mismatches of the other parameters.

4. The frequency response of the system is determined largely by the output filter when the pass band is restricted to less than  $\frac{1}{2}$  the sample rate. Above  $\frac{1}{2}$  the sample rate, the response is determined by the CVSD encoder and decoder pass band. The frequency selective measurement of the encoder/decoder response shows that the system is incapable of meeting the draft standard gain variation vs. frequency criteria given in figure 7a of Appendix A. The encoder and decoder alone have a response that falls off sharply above 4 kHz for the 16 kb/s sample rate, while the standard requires that the response not fall off more than 5 dB until 6 kHz is reached.

5. The specifications and tolerances given in the draft standard

appear adequate to assure reasonable system performance for voice signals. The transmitted signals will suffer some degradation due to parameter mismatches between the encoder and decoder. In most cases, the degradation is minimal, however, additional testing would be necessary to determine if the system response would continue to meet the draft standard criteria under mismatched conditions.

#### Recommendations

1. Since this model's performance is marginal under ideal conditions, parameter mismatch causes the performance to fall below the criteria set in the draft standard. Testing should be repeated using a filter that has higher stop band loss. The additional testing should concentrate on primary integrator response mismatches between the encoder and decoder, since the other parameters have little effect on the system response.

2. System tolerance to bit errors in the transmission system was not tested. A mismatch between the encoder and decoder may cause increased sensitivity to transmission errors. Testing to establish the system response to transmission bit error rate may be desirable.

3. The draft standard specifications for gain variation in the region between 4 kHz and 6 kHz for the 16 kb/s sample rate should be modified. Performance should be allowed to roll off as sharply as possible above 3.6 kHz.

4. Testing was performed using continuous sinusoidal test signals only. If quasi-analog signals are expected to be used on the CVSD system, testing should be repeated using this type of signal at various input keying speeds. Since the CVSD algorithm depends on the high sample to sample correlation characteristics of the voice signal, quasi-analog signals can be expected to suffer more degradation as the result of encoder/decoder mismatches. More restrictive tolerances may be necessary to assure adequate performance with these signals. In addition, more standards may be necessary, such as delay distortion specifications.

DRAFT STANAG

ON

THE ANALOGUE/DIGITAL CONVERSION OF  
SPEECH SIGNALS FOR  
TACTICAL, DIGITAL, AREA  
COMMUNICATIONS SYSTEMS

JUNE 1978

N A T O U N C L A S S I F I E D

-1-

N A T O U N C L A S S I F I E D

-2-

INTRODUCTION

This STANAG is one of a series, which, when taken as a whole, will specify the necessary technical parameters to allow digital, tactical area communications systems to interface.

This particular STANAG specifies the analogue/digital conversion of signals in the voice band to result in a digital bit rate of either 16 or 32 kbit/s per second. (32 kbits/sec in the interim period).

In order for two communications systems to interface they must use the same conversion process so that the speech signals may be re-constituted at the destination.

This STANAG specifies a delta coder/decoder (change in speech level is coded using syllabic companding controlled by a 3 bit logic).

N A T O U N C L A S S I F I E D

-2-

1. General

1.1 Analogue/digital conversion of telephone signals (speech or other voice-band signals) shall be performed by a delta coder/decoder using syllabic companding controlled by a three bit logic.

1.2 Block diagrams of the coder and decoder are shown in Figures 1 and 2.

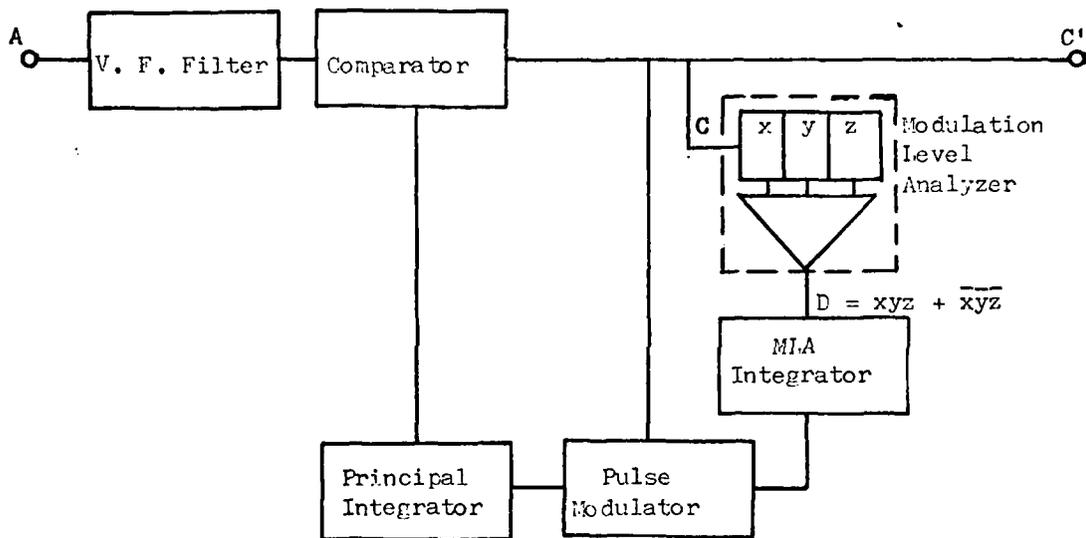

Fig. 1 - Block Schematic of the Coder

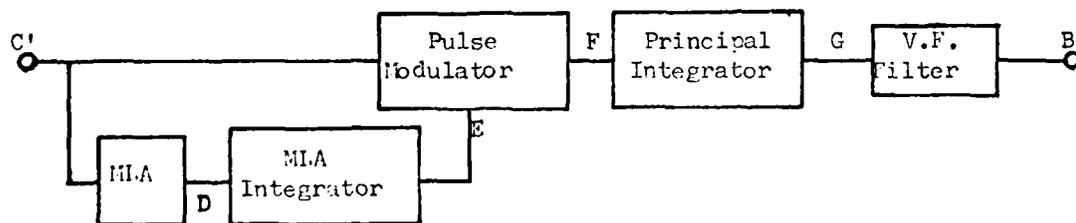

Fig. 2 - Block Schematic of the Decoder

2. Four-wire to Four-wire Audio Frequency Characteristics

2.1 Relative Level at Points A and B

The relative levels at points A and B shall be -4 dBr.

2.2 The absolute level is calculated by the equation  $\text{dBm} = \text{dBr} + \text{dBmO}$ .

2.3 Impedance at Points A and B

The nominal value of the impedance at points A and B shall be 600 ohms.

2.4 Return loss at Points A and B against 600 ohms

The return loss at points A and B shall be  $\geq 16$  dB in the frequency range from 300 Hz to 3400 Hz against a load resistor of 600 ohms with an input level of -20 dBmO.

2.5 Symmetry at Points A and B

Points A and B shall be balanced and not referred to ground, i.e. shall be floating.

3. Details of the Coder and Decoder Circuits

3.1 Input and Output Audio Filters

For frequencies above 6 kHz, each filter shall have an attenuation of  $\geq 25$  dB.

3.2 Frequency Response of the Principal Integrator

The ideal amplitude frequency characteristic between points F and G is shown in Figure 3.

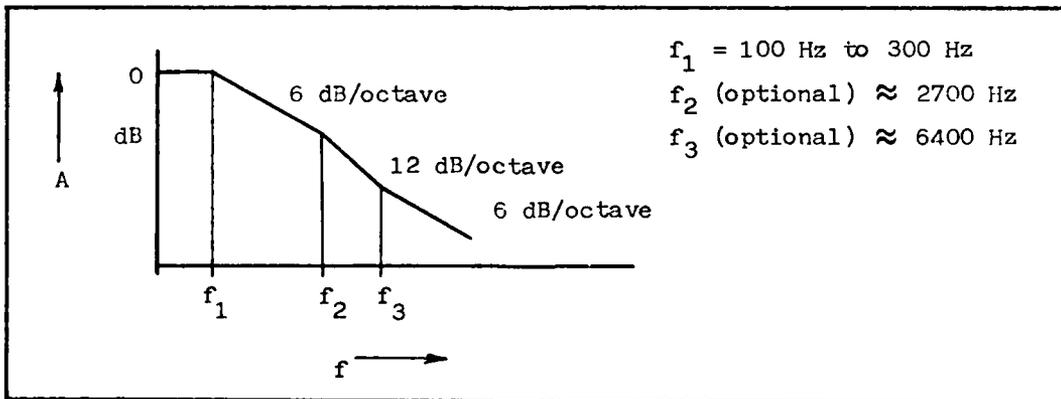

Fig. 3 - Ideal Amplitude Frequency Characteristic of the Principal Integrator

3.3      Modulation Level

A signal of 800 Hz and 0 dBm0, applied to point A of the coder shall give a duty cycle (mean proportion of binary '1' digits at point D each one indicating a run of 3 equal bits at point C) of  $c_d = 0.5$  at point D of the modulation level analyzer (MLA).

3.4      Compression and Expansion

In the coder and decoder the quantizing step size  $q$  which drives the principle integrator at Point F, shall have an essentially linear relationship to the duty cycle at point D of the MLA integrator (see Figure 4).

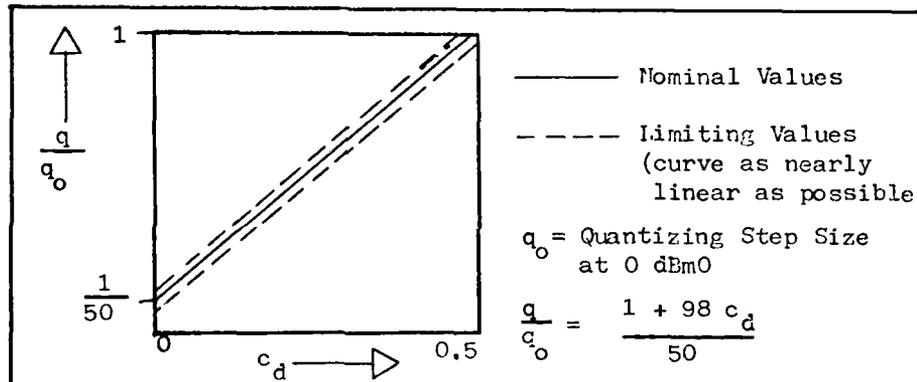

Fig. 4 - Relation between MLA Output Duty Cycle and Size of Quantizing Steps

It follows that the ratio of the quantizing step size at point F corresponding to a duty cycle of  $c_d = 0.5$  at point D of the MLA integrator at the minimum step size  $q_0$  shall be 34 dB (provisional tolerance:  $\pm 2$ dB).

3.5      Companding Speed

The following is valid for the condition that C is connected to C'. When an 800 Hz sine wave signal at point A is suddenly changed from -42 dBm0 to 0 dBm0 the output signal at point B shall reach 90% of its final value within 2 ms to 4 ms.

NOTE:-

The MLA integrator circuits of the coder and decoder shall have the same characteristics and hence the same companding speed.

3.6 Procedure for Testing the Delta Decoder

The test bit sequence generator is connected to the decoder input point C' (see Figure 2).

Testing is performed by means of periodical test bit sequences (listed in Table 1) which result in audio signals at 800 Hz at the decoder output point B. The 800 Hz levels at point B shall conform to the values given in Table 1.

When the signal at point C' is switched from the periodical test bit sequence to the periodical test bit sequence g, then the output signal at point B shall reach 90% of its final value within 5.5 mS to 11.5 mS. When the signal at point C' is switched from the periodical test bit sequence g to the periodical test bit sequence a, then the output signal at point B shall reach 10% of the value of the periodical test bit sequence g within 4 mS to 8mS.

NOTE:- for clarification

For an RC circuit in the MIA integrator with time constants of 4 mS for both charging and discharging, the envelope characteristic of the output signal at point B is shown in Figure 5. For the case of switching the signal at point C' from the sequence g to sequence a, the amplitude at the beginning of discharging is at the first moment after switching higher - by a factor of 50 - than the final value which is reached asymptotically. The final value equals -42 dBm0, i.e. 0.00794, the amplitude at the beginning of the discharging is hence 0.397 ( $c_d = 0$ ). The value of 10% is then reached at 5.76 mS.

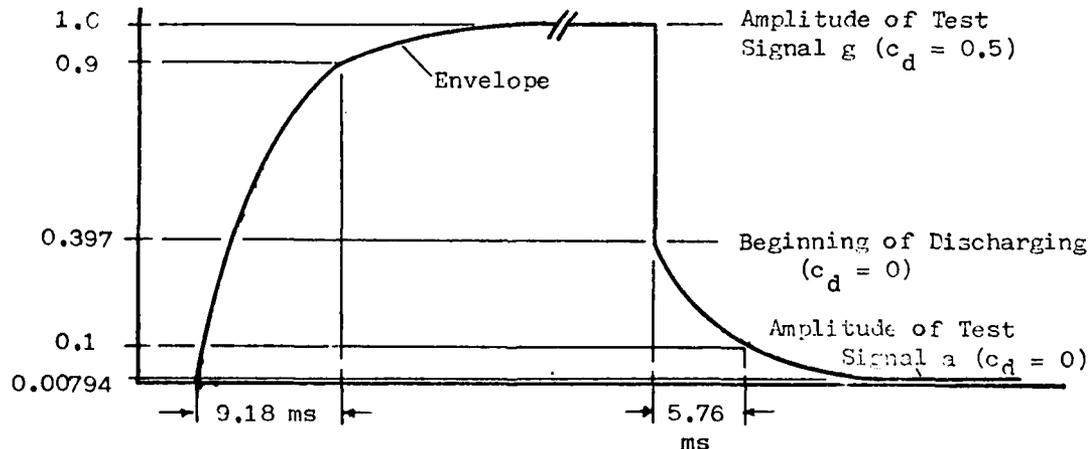

Fig. 5 - Envelope Characteristic of the Output Signal at Point B (Half the Envelope)

$c_d$  Duty cycle at point D of the modulation level analyzer (MLA)

(1) Sequence of 20 bits for a digit rate of 16 kbits/s

(2) Sequence of 40 bits for a digit rate of 32 kbits/s

x) For the relative level see para. 2.1 above.

4. Electrical Performance at Points A and B

4.1 General

The required values under 4.2 to 4.8 are valid for the condition that C is connected to C'.

For measurement, the input (point A) and the output (point B) are to be terminated with 600 ohms, and signals whose frequencies are sub-multiples of the sampling rate shall be avoided. Accordingly, where a nominal test signal frequency of 800 Hz is indicated, the actual frequency shall be slightly different; a preferred value is 820 Hz, but frequencies from 804 to 860 Hz.

The measurements according to Sections 4.2 to 4.5 shall be performed selectively.

4.2 Insertion Loss between Points A and B

The insertion loss between points A and B at 800 Hz with an input level of 0 dBm0 shall be  $0 \text{ dBm0} \pm 2 \text{ dB}$ . The insertion loss contributed by the transmit and receive sides shall not exceed one-half of the value.

4.3 Attenuation Distortion with Frequency

The attenuation distortion relative to 800 Hz measured with an input level of -20 dBm0 applied to point A shall be within the limits of Figure 6. The distortion contributed by the transmit side alone, measured at point G of the coder, shall not exceed the limits indicated by the broken lines in Figure 6.

4.4 Variation of Gain with Input Level

The deviation of the output level compared with the value at -20 dBm0 shall not exceed the limits given in Figure 7 for a frequency of 800 Hz.

4.5 Idle Channel Noise

Idle channel noise at 16 kbits/s:

The idle channel noise at point B shall not exceed -45 dBm0p. The level of any single frequency, measured selectively, shall not exceed -50 dBm0 in the frequency range from 0.3 kHz to 8 kHz.

Idle channel noise at 32 kbit/s:-

The idle channel noise at point B shall not exceed -60 dBmOp. The level of any single frequency, measured selectively, shall not exceed -65 dBmO in the frequency range from 0.3 kHz to 16 kHz.

4.6 Variation of Quantization and Harmonic Distortion with Input Level

The distortion shall be measured unweighted with a sinewave test signal at 800 Hz. With such a signal applied to point A, the ratio of signal to distortion power at the output point B shall be above the limits of Figure 8.

4.7 Variation of Quantizing and Harmonic Distortion with Frequency

The distortion shall be measured unweighted with a sinewave test signal of -20 dBmO. With such a test signal applied to point A, the ratio of signal to distortion power at the output point B shall be above the limits of Figure 9.

APPENDIX H

Syllabic Filter Output vs. Slope Overload Detector Duty Cycle

```

PROGRAM STEPSZ(INPUT,OUTPUT,TAPES=INPUT,TAPES=OUTPUT,PLOT)
-----STEP SIZE CALCULATION-----
THIS PROGRAM CALCULATES THE STEP SIZE OUTPUT OF THE SYLLABIC FILTER USED IN THE CUSD ENCODER AND DECODER. THE STEP SIZE DETERMINED AS A FUNCTION OF THE SLOPE OVERLOAD DETECTOR OUTPUT DUTY CYCLE. THE DETECTOR DUTY CYCLE IS LIMITED FROM 0 TO .5 AND THE AVERAGE SYLLABIC FILTER OUTPUT AMPLITUDE IS CALCULATED AND PLOTTED. THE CALCULATIONS ARE PERFORMED FOR BOTH 19 AND 32 KB/S SAMPLE RATES AND THE DATA PLOTTED ON THE SAME GRAPH.

***** VARIABLES *****

CD = A REAL ARRAY CONTAINING THE DUTY CYCLE POINTS AT WHICH CALCULATION OF THE AVERAGE STEP SIZE IS PERFORMED.

STEP = A REAL ARRAY CONTAINING THE AVERAGE STEP SIZES

UMAX = A REAL VARIABLE USED AS THE INPUT TO THE SYLLABIC FILTER TO DETERMINE THE MAXIMUM STEP SIZE.

UMIN = A REAL VARIABLE USED AS THE INPUT TO THE SYLLABIC FILTER TO DETERMINE THE MINIMUM STEP SIZE.

FS = THE SAMPLE RATE BEING USED.

TC = THE TIME CONSTANT OF THE SYLLABIC FILTER.

BETA = THE DECAY RATE OF THE OUTPUT OF THE SYLLABIC FILTER DURING ONE TIME STEP.

I, J = COUNTING INDICES FOR THE "DO" LOOPS.

DELTA = THE CURRENT VALUE OF THE STEP SIZE.

SUM = A RUNNING TOTAL OF THE STEPS CALCULATED TO BE USED FOR AVERAGING.

U = THE CURRENT VALUE OF THE INPUT TO THE SYLLABIC FILTER.

JDI, JT = INTEGER VARIABLES USED IN CALCULATING WHEN THE INPUT TO THE SYLLABIC FILTER SHOULD BE CHANGED FROM UMIN TO UMAX. THE INPUT IS UMAX FOR "ITH" "J".

CVSD System Step Response Program

```

PROGRAM PULSE(INPUT,OUTPUT,TAPES-OUTPUT,PLOT)
C THIS PROGRAM PLOTS THE OUTPUT SIGNAL OF THE CVSD TRANSMISSION
C SYSTEM WHEN THE INPUT SIGNAL IS A 800 HERTZ SINE WAVE
C THAT VARIES IN AMPLITUDE FROM -42 DBM0 TO 0 DBM0. THE TEST
C SIGNAL GENERATOR ALTERNATELY GENERATES 500 SAMPLES AT -42 DBM0
C AND 0 DBM0 IN ORDER TO DEMONSTRATE THE SYSTEM'S STEP RESPONSE
C CHARACTERISTICS. THE SYSTEM UNDER TEST CONSISTS OF THE INPUT
C FILTER,THE CVSD ENCODER AND DECODER, AND THE OUTPUT FILTER.

C***** VARIABLES *****
C TSIN = AN ARRAY CONTAINING THE INPUT TIME SERIES SAMPLES.
C TSOUT = AN ARRAY CONTAINING FIRST THE DECODER OUTPUT TIME SERIES
C SAMPLES, THEN THE OUTPUT TIME SERIES SAMPLES OF THE FIR FILTER.
C B = AN ARRAY CONTAINING THE FILTER COEFFICIENTS.
C TIME = AN ARRAY CONTAINING THE TIME THAT THE FIRST 200 SAMPLES
C ARE TAKEN SO THAT THEY MAY BE PLOTTED.
C BINOUT = AN ARRAY CONTAINING THE BINARY OUTPUT OF THE CVSD ENCODER
C AMP1 = THE AMPLITUDE OF THE TEST SIGNAL IN DBM0.
C FS = THE SAMPLE RATE.
C FC1, FC2, FC3 = THE ROLL-OFF FREQUENCIES OF THE PRIMARY INTEGRA-
C TORS.
C TC = THE TIME CONSTANT OF THE SYLLABIC FILTERS.
C UMAX & UMIN = THE MAXIMUM AND MINIMUM INPUTS TO THE SYLLABIC FIL-
C TER.
C BETA = THE NORMALIZED CENTER OF THE TRANSITION BAND OF THE LOW
C PASS FILTER.
C GAMMA = THE NORMALIZED WIDTH OF THE ROLL-OFF REGION OF THE OUTPUT
C FILTER. THE REGION IS THE FREQUENCY BAND BETWEEN THE 95% AND
C 5% OUTPUT AMPLITUDES.
C PEAK1 = THE MAXIMUM AMPLITUDE OF THE TEST SIGNAL IN VOLTS.
C NP = THE NUMBER OF FILTER COEFFICIENTS.
C DC = THE DUTY CYCLE OF THE SLOPE OVERLOAD DETECTOR.
C RATIO = THE RATIO BETWEEN THE MAXIMUM STEP SIZE AND THE MINIMUM
C STEP SIZE IN DB
C***** SUBROUTINES USED *****

APPENDIX L

Idle Channel Noise Program

PROGRAM IDLENOI(INPUT,OUTPUT,TAPES-OUTPUT,PLOT)

-----IDLE CHANNEL NOISE PROGRAM-----

C THIS PROGRAM MEASURES THE IDLE CHANNEL NOISE OF THE CUSD TRANSMISSION SYSTEM WHEN THE ENCODER AND DECODER ARE CONNECTED BACK-TO-BACK AND THE INPUT TO THE ENCODER IS GROUNDING.

C THE SYSTEM GAIN IS ADJUSTED SO THAT AN 800 KHZ INPUT SIGNAL AT -20 DBM PRODUCES A -20 DBM SIGNAL AT THE OUTPUT OF THE DECODER.

C##### VARIABLES #####

C FREQ1 = THE REFERENCE FREQUENCY USED TO SET THE SYSTEM GAIN.

C TSIN = AN ARRAY CONTAINING THE INPUT TIME FUNCTION SAMPLES.

C TSOUT = AN ARRAY CONTAINING FIRST THE DECODER OUTPUT TIME FUNCTION SAMPLES, THEN THE OUTPUT TIME FUNCTION SAMPLES OF THE FIR FILTER

C B = AN ARRAY CONTAINING THE FILTER COEFFICIENTS.

C BINOUT = AN ARRAY CONTAINING THE BINARY OUTPUT OF THE CUSD ENCODER

C AMP1 = THE AMPLITUDE OF THE REFERENCE SIGNAL IN DBM.

C FS = THE SAMPLE RATE.

C FC1, FC2, FC3 = THE ROLL-OFF FREQUENCIES OF THE PRIMARY INTEGRATORS.

C TC = THE TIME CONSTANT OF THE SYLLABIC FILTERS.

C UMAX & UMIN = THE MAXIMUM AND MINIMUM INPUTS TO THE SYLLABIC FILTER.

C BETA = THE NORMALIZED 3 DB FREQUENCY OF THE OUTPUT FILTER. THE FREQUENCY IS NORMALIZED TO THE SAMPLE RATE.

C GAMMA = THE NORMALIZED WIDTH OF THE ROLL-OFF REGION OF THE OUTPUT FILTER. THE REGION IS THE FREQUENCY BAND BETWEEN THE 66% AND 8% OUTPUT AMPLITUDES.

C PEAK1 = THE MAXIMUM AMPLITUDE OF THE TEST SIGNAL IN VOLTS.

C NP = THE NUMBER OF FILTER COEFFICIENTS.

C DC = THE DUTY CYCLE OF THE SLOPE OVERLOAD DETECTOR.

C PIN = THE POWER OF THE INPUT SIGNAL IN DBM.

C POUT = THE POWER OF THE OUTPUT SIGNAL IN DBM.

C ICH = THE CALCULATED IDLE CHANNEL NOISE IN DBM.

C GAIN = THE VOLTAGE AMPLIFICATION OF THE SYSTEM.

##### SUBROUTINES USED #####

C FLTRGEN = THE SUBROUTINE THAT GENERATES THE OUTPUT FILTER COEFFICIENTS.

C SIGNAL = THE TEST SIGNAL GENERATOR

C ENCODE1 = THE CUSD ENCODER

C DECODE1 = THE CUSD DECODER

C FILTER = THE SUBROUTINE THAT FILTERS THE INPUT TIME FUNCTION SAMPLES USING THE FILTER COEFFICIENTS GENERATED BY FLTRGEN.

C POWER = A ROUTINE TO CALCULATE THE POWER IN A SAMPLED TIME FUNCTION WITH IMPEDANCE = 600 OHMS.

APPENDIX M

Total Harmonic Distortion Program

PROGRAM HARDIST(INPUT,OUTPUT,TAPES=INPUT,TAPES=OUTPUT)

-----TOTAL HARMONIC DISTORTION PROGRAM-----

THIS PROGRAM CALCULATES THE TOTAL HARMONIC DISTORTION IN THE OUTPUT WHEN A SINGLE FREQUENCY TEST SIGNAL IS PROCESSED THROUGH A CUSD ENCODER AND DECODER CONNECTED BACK-TO-BACK. DISTORTION IS CALCULATED USING ONLY THOSE SPECTRAL COMPONENTS OF THE OUTPUT THAT LIE BETWEEN 100 HZ AND 4000 HZ. TONES AT EXACTLY 100 HZ OR 4000 HZ ARE NOT INCLUDED IN THE CALCULATION.

\*\*\*\*\* VARIABLES \*\*\*\*\*

- C INPUT - AN INTEGER ARRAY CONTAINING THE BINARY OUTPUT OF THE CUSD ENCODER.
- C OUTPUT - A REAL ARRAY CONTAINING THE TIME FUNCTION OUTPUT OF THE TEST SIGNAL GENERATOR AND AFTER PROCESSING, THE TIME FUNCTION OUTPUT OF THE DECODER.
- C PSX - A REAL ARRAY CONTAINING THE OUTPUT SPECTRAL POWER COMPONENTS OF THE DECODER OUTPUT AFTER PROCESSING BY THE FAST FOURIER TRANSFORM SUBROUTINE.
- C IUK, UK, CUK - WORKING ARRAYS USED BY THE FFT SUBROUTINE.
- C FREQUE - A REAL ARRAY CONTAINING THE FREQUENCIES AT WHICH THE FFT HAS CALCULATED THE SPECTRAL COMPONENTS.
- C FREQ - THE FREQUENCY OF THE TEST SIGNAL IN HZ.
- C AMP - THE AMPLITUDE OF THE TEST SIGNAL IN DBM.
- C FS - THE SAMPLE RATE IN SPS.
- C A - THE PEAK VALUE OF THE TEST SIGNAL.
- C FC1, FC2, FC3 - ROLL-OFF FREQUENCIES FOR THE PRINCIPLE INTEGRATOR IN THE CUSD ENCODER AND DECODER.
- C TC - THE COMPANDING SPEED OF THE SYLLABIC INTEGRATOR IN SEC.
- C F - A FREQUENCY VARIABLE USED TO DETERMINE THE TEST SIGNAL SPECTRAL COMPONENT AND ALSO TO DETERMINE THE HARMONIC SPECTRAL COMPONENTS.
- C EO - THE RMS POWER OF THE OUTPUT SPECTRAL COMPONENT AT THE TEST FREQUENCY.
- C REF - THE OUTPUT SPECTRAL COMPONENT POWER IN DBM.
- C SUM - THE RUNNING SUM OF THE POWER OF THE HARMONIC COMPONENTS.
- C THD - THE TOTAL HARMONIC DISTORTION IN %.
- C BETA - NORMALIZED 3 DB FREQUENCY OF THE OUTPUT FILTER
- C GAMMA - THE NORMALIZED ROLL-OFF BANDWIDTH OF THE OUTPUT FILTER
- C RATIO - THE RATIO OF THE MAXIMUM STEP SIZE TO THE MINIMUM STEP SIZE IN THE CUSD ENCODER AND DECODER, GIVEN ON DB.

\*\*\*\*\* SUBROUTINES USED \*\*\*\*\*

- 1 ENCODE1 - THE CUSD ENCODER
- 2 DECODE1 - THE CUSD DECODER
- C UMAXOPT - GENERATES UMAX AND UMIN USED IN THE CUSD ENCODER AND DECODER
- C FLTERGEN - THE COEFFICIENT GENERATOR FOR THE OUTPUT FILTER
- C FILTER - FILTERS THE OUTPUT SIGNAL.
- C FTFPS - THE FAST FOURIER TRANSFORM SUBROUTINE FROM THE INEL LIBRARY

Mismatched Signal-to-Noise Ratio vs. Input Signal Frequency

```

PROGRAM MMSNR(INPUT,OUTPUT,TAPES=OUTPUT,PLOT)
-----MISMATCHED SNR PROGRAM-----
C
C THIS PROGRAM MEASURES THE SIGNAL-TO-NOISE PERFORMANCE OF A CUSD
C ENCODER AND DECODER CONNECTED BACK-TO-BACK. A SINGLE FREQUENCY
C SINE WAVE IS INPUT TO THE SYSTEM AND THE DIFFERENCE BETWEEN THE
C OUTPUT AND INPUT COMPUTED.
C
C THE CALCULATIONS ARE PERFORMED AS THE VALUE OF THE ENCODER STEP
C SIZE RATIO IS KEPT CONSTANT AND THE DECODER STEP SIZE RATIO IS
C CHANGED. THE ENCODER RATIO IS 32 DB, WHILE THE DECODER IS STEPPED
C FROM 32 TO 36 DB IN STEPS OF 2 DB.
C
C A MAXIMALLY FLAT LINEAR PHASE FIR FILTER IS PLACED ON THE OUTPUT
C OF THE DECODER TO REMOVE SIGNAL COMPONENTS ABOVE 3600 KHZ.
C
C***** VARIABLES *****
C
C FREQ1 = AN ARRAY CONTAINING THE FREQUENCIES THAT THE SNR HAS BEEN
C MEASURED AT. THE RANGE IS 300 KHZ TO 3000 KHZ.
C
C SNR = AN ARRAY CONTAINING THE MEASURED SNR VALUES.
C
C TSIN = AN ARRAY CONTAINING THE INPUT TIME SERIES SAMPLES.
C
C TSOUT = AN ARRAY CONTAINING FIRST THE DECODER OUTPUT TIME SERIES
C SAMPLES, THEN THE OUTPUT TIME SERIES SAMPLES OF THE FIR FILTER.
C
C ERR = AN ARRAY CONTAINING THE DIFFERENCE BETWEEN THE OUTPUT SAM-
C PLES AND THE INPUT SAMPLES.
C
C B = AN ARRAY CONTAINING THE FILTER COEFFICIENTS.
C
C TIME = AN ARRAY CONTAINING THE TIME THAT THE FIRST 200 SAMPLES
C ARE TAKEN SO THAT THEY MAY BE PLOTTED.
C
C BINOUT = AN ARRAY CONTAINING THE BINARY OUTPUT OF THE CUSD ENCODER
C
C AMP1 = THE AMPLITUDE OF THE TEST SIGNAL IN DBM0.
C
C FS = THE SAMPLE RATE.
C
C FC1, FC2, FC3 = THE ROLL-OFF FREQUENCIES OF THE PRIMARY INTEGRA-
C TORS.
C
C TC = THE TIME CONSTANT OF THE SYLLABIC FILTERS.
C
C UMAX & URIN = THE MAXIMUM AND MINIMUM INPUTS TO THE SYLLABIC FIL-
C TER.
C
C BETA = THE NORMALIZED 3 DB FREQUENCY OF THE OUTPUT FILTER. THE
C FREQUENCY IS NORMALIZED TO THE SAMPLE RATE.
C
C GAMMA = THE NORMALIZED WIDTH OF THE ROLL-OFF REGION OF THE OUTPUT
C FILTER. THE REGION IS THE FREQUENCY BAND BETWEEN THE 55% AND
C 6% OUTPUT AMPLITUDES.
C
C NP = THE NUMBER OF FILTER COEFFICIENTS.
C
C KN = THE NUMBER OF TEST FREQUENCIES.
C
C DC = THE DUTY CYCLE OF THE SLOPE OVERLOAD DETECTOR.
C*****
C
C FLTRGEN = THE SUBROUTINE THAT GENERATES THE OUTPUT FILTER COEFFI-
C CIENTS.
C
C PLOT, SCALE, AXIS, RECT, LINE, PLOTE, = CALCOMP PLOTTING ROUTINES.
C
C SIGNAL = THE TEST SIGNAL GENERATOR. PRODUCES SAMPLES OF SINUSOI-
C DAL WAVES WITH AT MOST TWO FREQUENCY COMPONENTS.
C
C ENCODE1 = THE CUSD ENCODER SUBROUTINE WITH A SINGLE ROLL-OFF
C FREQUENCY IN THE PRIMARY INTEGRATOR.
C
C DECODE1 = THE CUSD DECODING SUBROUTINE WITH A SINGLE ROLL-OFF
C FREQUENCY IN THE PRIMARY INTEGRATOR.

```

```

C   FILTER = THE SUBROUTINE THAT FILTERS THE INPUT TIME SERIES SAMPLES
C   USING THE FILTER COEFFICIENTS GENERATED BY FLTRGEN.

C   POWER = A ROUTINE TO CALCULATE THE POWER IN A SAMPLED TIME SERIES
C   WITH IMPEDENCE = 600 OHMS.

C   PLTIME = A LINEAR PLOTTING ROUTINE TO PLOT SIGNAL AMPLITUDE VS.
C   TIME.

Flat Weighted Frequency Response Program  
PROGRAM DIGGAIN(INPUT,OUTPUT,TAPE6-OUTPUT,PLOT)

-----DIFFERENTIAL GAIN PROGRAM-----

THIS PROGRAM MEASURES THE SYSTEM GAIN VS. FREQUENCY RESPONSE FOR  
A CUSD DIGITAL/ANALOG SYSTEM CONNECTED BACK-TO-BACK.  
A MAXIMALLY FLAT LINEAR PHASE FIR FILTER IS PLACED ON THE OUTPUT  
OF THE DECODER TO REMOVE SIGNAL COMPONENTS ABOVE 3600 HZ.

\*\*\*\*\* VARIABLES \*\*\*\*\*

- C    FREQ1 = AN ARRAY CONTAINING THE FREQUENCIES THAT THE SNR HAS BEEN  
C        MEASURED AT. THE RANGE IS 300 HZ TO 3300 HZ.
- C    TSIN = AN ARRAY CONTAINING THE INPUT TIME FUNCTION SAMPLES.
- C    TSOUT = AN ARRAY CONTAINING FIRST THE DECODER OUTPUT TIME FUNCTION  
C         SAMPLES, THEN THE OUTPUT TIME FUNCTION SAMPLES OF THE FIR FIL-  
C         TER.
- C    B = AN ARRAY CONTAINING THE FILTER COEFFICIENTS.
- C    BINOUT = AN ARRAY CONTAINING THE BINARY OUTPUT OF THE CUSD ENCODER
- C    AMP1 = THE AMPLITUDE OF THE TEST SIGNAL IN DBM0.
- C    FS = THE SAMPLE RATE.
- C    FC1, FC2, FC3 = THE ROLL-OFF FREQUENCIES OF THE PRIMARY INTEGRA-  
C         TORS.
- C    TC = THE TIME CONSTANT OF THE SYLLABIC FILTERS.
- C    UMAX & UMIN = THE MAXIMUM AND MINIMUM INPUTS TO THE SYLLABIC FIL-  
C         TER.
- C    BETA = THE NORMALIZED CENTER FREQUENCY OF THE OUTPUT FILTER TRANS-  
C         ITION BAND.
- C    GAMMA = THE NORMALIZED WIDTH OF THE ROLL-OFF REGION OF THE OUTPUT  
C         FILTER. THE REGION IS THE FREQUENCY BAND BETWEEN THE 95% AND  
C         5% OUTPUT AMPLITUDES.
- C    PEAK1 = THE MAXIMUM AMPLITUDE OF THE TEST SIGNAL IN VOLTS.
- C    NP = THE NUMBER OF FILTER COEFFICIENTS.
- C    KN = THE NUMBER OF TEST FREQUENCIES.
- C    DC = THE DUTY CYCLE OF THE SLOPE OVERLOAD DETECTOR.

\*\*\*\*\* SUBROUTINES USED \*\*\*\*\*

- C    FLTRGEN = THE SUBROUTINE THAT GENERATES THE OUTPUT FILTER COEFFI-  
C         CIENTS.

Mismatched Flat Volterra Frequency Response Program

PROGRAM MMDGAIN(INPUT,OUTPUT,TAPE6-OUTPUT,PLOT)

```

C-----MISMATCHED SYSTEM GAIN RESPONSE-----
C
C THIS PROGRAM MEASURES THE SYSTEM GAIN VS. FREQUENCY RESPONSE FOR
C A CUSD DIGITAL/ANALOG SYSTEM CONNECTED BACK-TO-BACK.
C
C A MAXIMALLY FLAT LINEAR PHASE FIR FILTER IS PLACED ON THE OUTPUT
C OF THE DECODER TO REMOVE SIGNAL COMPONENTS ABOVE 3500 HZ.
C
C***** VARIABLES *****
C
C FREQ1 = AN ARRAY CONTAINING THE FREQUENCIES THAT THE SNR HAS BEEN
C MEASURED AT. THE RANGE IS 300 HZ TO 3500 HZ.
C
C TSIN = AN ARRAY CONTAINING THE INPUT TIME FUNCTION SAMPLES.
C
C TSOUT = AN ARRAY CONTAINING FIRST THE DECODER OUTPUT TIME FUNCTION
C SAMPLES, THEN THE OUTPUT TIME FUNCTION SAMPLES OF THE FIR FIL-
C TER.
C
C B = AN ARRAY CONTAINING THE FILTER COEFFICIENTS.
C
C BINOUT = AN ARRAY CONTAINING THE BINARY OUTPUT OF THE CUSD ENCODER
C
C AMP1 = THE AMPLITUDE OF THE TEST SIGNAL IN DBM0.
C
C FS = THE SAMPLE RATE.
C
C FC1, FC2, FC3 = THE ROLL-OFF FREQUENCIES OF THE PRIMARY INTEGRA-
C TORS.
C
C TC = THE TIME CONSTANT OF THE SYLLABIC FILTERS.
C
C UMAX & UMIN = THE MAXIMUM AND MINIMUM INPUTS TO THE SYLLABIC FIL-
C TER.
C
C BETA = THE NORMALIZED CENTER FREQUENCY OF THE OUTPUT FILTER TRANS-
C ISSION BAND.
C
C GAMMA = THE NORMALIZED WIDTH OF THE ROLL-OFF REGION OF THE OUTPUT
C FILTER. THE REGION IS THE FREQUENCY BAND BETWEEN THE 95% AND
C 5% OUTPUT AMPLITUDES.
C
C PEAK1 = THE MAXIMUM AMPLITUDE OF THE TEST SIGNAL IN VOLTS.
C
C NP = THE NUMBER OF FILTER COEFFICIENTS.
C
C NF = THE NUMBER OF TEST FREQUENCIES.
C
C DC = THE DUTY CYCLE OF THE SLOPE OVERLOAD DETECTOR.
C*****
C***** SUBROUTINES USED *****
C
C FLTRGEN = THE SUBROUTINE THAT GENERATES THE OUTPUT FILTER COEFFI-
C CIENTS.
C
C PLOT, SCALE, AXIS, RECT, LINE, PLOTE, = CALCOMP PLOTTING ROUTINES.

      END
```

Vita

Jeffrey Allan Iersch was born 20 January 1948 in Milwaukee, Wisconsin. After graduating from New Berlin High School in 1966, he began undergraduate study in electrical engineering at Michigan Technological University. Captain Iersch received his Bachelor of Science degree in electrical engineering and was commissioned in the Air Force in June 1971. His entire Air Force career has been as an engineer working with the military long-haul communications system, first at Headquarters Air Force Communications Service, then in Athens, Greece with the 2140th Communications Group, and finally at the Headquarters Northern Communications Area at Griffiss AFB, New York. In June 1979 Captain Iersch began study at the Air Force Institute of Technology for a Master of Science degree in electrical engineering.

20. ABSTRACT (Continue on reverse side if necessary and identify by block number) A computer model of the continuously variable slope delta voice encoding system specified in the draft STAPAG on "Analogue/Digital Conversion of Speech Signals for Tactical, Digital, Area Communications Systems", dated June 1978, is developed and implemented in FORTRAN IV. The model's performance is then characterized in terms of idle channel noise, total harmonic distortion, intermodulation distortion, signal-to-noise ratio, and frequency response. For each of these attributes, the system's performance is presented graphically and compared to the criteria established

Item 20 continued.

In the draft standard, The model is then exercised by varying the system parameters to the limits imposed by the standard and the resulting performance compared to the previously determined ideal system performance. The results show that the performance characteristics measured are most sensitive to the primary integrator response and output filter response when the system parameters are restricted to the range allowed by the draft NATO standard.
